#### CHAPTER 1

1-1

$$\frac{dq(t)}{dt} = -\frac{8}{50} q(t) \qquad (b)$$

$$\frac{dp(t)}{dt} = \frac{8}{50} q(t) - \frac{8}{50} p(t). \qquad (b)$$

(c)
$$A = \begin{bmatrix} -.16 & 0 \\ .16 & -.16 \end{bmatrix} \longrightarrow \begin{bmatrix} s \pm -A \end{bmatrix}^{-1} = \Phi(s) = \underbrace{\begin{bmatrix} s + .16 & 0 \\ .16 & s + .16 \end{bmatrix}}_{\begin{bmatrix} s + .16 \end{bmatrix}^{2}}$$

Taking the inverse Laphce transform of each element of \$\Pi(s)\$ yields

$$\varphi(t) = \begin{bmatrix} e^{-.16t} & o \\ .16te^{-.16t} & e^{-.16t} \end{bmatrix}.$$

(d) 
$$\begin{bmatrix} g(t) \\ p(t) \end{bmatrix} = p(t) \begin{bmatrix} g(0) \\ p(0) \end{bmatrix} = \begin{bmatrix} 60e^{-1/6t} \\ 9.6te^{-1/6t} \end{bmatrix}$$

1-2

(a) Application of Kirchhoff's voltage law gives  $e(t) = Ri_{L}(t) + L \frac{di_{L}(t)}{dt} + N_{E}(t), \quad (\pm)$ in addition

In addition 
$$\frac{dt}{dv_{e}(t)/dt} = \frac{1}{c} i_{L}(t)$$
. (II)

$$\frac{di_{L}(t)}{dt} = -\frac{R}{L}i_{L}(t) - \frac{1}{L}N_{C}(t) + \frac{1}{L}e(t)$$

$$\frac{dN_{C}(t)}{dt} = \frac{1}{C}i_{L}(t).$$

(b) 
$$A = \begin{bmatrix} -\frac{1}{L} & -\frac{1}{L} \\ \frac{1}{L} & 0 \end{bmatrix}$$
  $\begin{bmatrix} 5\frac{\pi}{L} - A \end{bmatrix}^{-1} = \Phi(5) = \begin{bmatrix} 5 & -1 \\ 2 & 5+3 \end{bmatrix}$   $\det \begin{bmatrix} 5\frac{\pi}{L} - A \end{bmatrix}$   $\Phi(t) = \begin{bmatrix} -e^{-t} + 2e^{-2t} & e^{-2t} - e^{-t} \\ 2[e^{-t} - e^{-2t}] & 2e^{-t} - e^{-2t} \end{bmatrix}$ .

$$\begin{bmatrix} I_{L}(s) \\ V_{c}(s) \end{bmatrix} = \bigoplus_{n=0}^{\infty} (s) \underbrace{B}_{L} U(s) = \underbrace{\begin{bmatrix} \frac{s}{(s+1)} \underbrace{Cs+2} \\ \frac{2}{s} \end{bmatrix}}_{\frac{s}{s}} \underbrace{\begin{bmatrix} e^{-s} - e^{-2s} \end{bmatrix}}_{\frac{s}{s}}$$

$$i_{L}(t) = 2\left[e^{-\frac{1}{L}-0} - e^{-2\left[t-\frac{1}{L}\right]} \frac{1}{4}(t-1) - 2\left[e^{-\frac{1}{L}-2} - e^{-2\left[t-\frac{1}{L}\right]} \frac{1}{4}(t-1) - 4\left[t-e^{-\frac{1}{L}-2} + t\right] e^{-2\left[t-\frac{1}{L}\right]} \frac{1}{4}(t-1) - 4\left[t-e^{-\frac{1}{L}-2} + t\right] e^{-2\left[t-\frac{1}{L}\right]} e^{-2\left[t-\frac{1}{L}$$

4-3

(a) Nÿ(t) = f(t) - Ky(t) - By(t) ; letting x(t) = y(t) x2(t) ≜ jt), we have

$$\dot{x}_{1}(t) = x_{2}(t)$$
  $\dot{x}_{2}(t) = -\frac{k}{M}x_{1}(t) - \frac{k}{M}x_{2}(t) + \frac{k}{M}f(t)$ .

(b)  $\dot{x}_{1}(t) = x_{2}(t)$   $\dot{x}_{2}(t) = -\frac{k}{M}x_{1}(t) - \frac{k}{M}x_{2}(t) + \frac{k}{M}f(t)$ .

$$\mathcal{P}(t) = \mathcal{L}^{-1} \left[ \frac{\Phi(s)}{2} \right] = \begin{bmatrix} \sqrt{2} & e^{-t} \cos(t - \pi/4) & e^{-t} \sin(t) \\ -2 & e^{-t} \sin(t) & \sqrt{2} & e^{-t} \cos(t + \pi/4) \end{bmatrix}$$

$$\Phi(s) \not B U(s) = 
\begin{bmatrix}
2 \\
[s+2][s^2+2s+2]
\end{bmatrix}$$

$$2 s
[s+2][s^2+2s+2]$$

$$\mathcal{J}^{-1}\left\{\bigoplus_{s} |S| \mathcal{B} |U(s)\right\} = \begin{bmatrix} e^{-2t} + \sqrt{2} e^{-t} \cos(t - 3\pi/4) \\ -2e^{-2t} + 2e^{-t} \cos(t) \end{bmatrix}$$

The initial-condition response is given by X(t) = 9(t) X(0), so the total response is

y|t) = 
$$0.2\sqrt{2}$$
  $e^{-t}\cos(t-\pi/4)+e^{-2t}+\sqrt{2}e^{-t}\cos(t-\pi/4)$ 

$$\dot{y}(t) = -0.4e^{-t} \sin(t) - 2e^{2t} + 2e^{-t}\cos(t)$$
.

1-4 Applying Kirchhoff's voltage law (KVL) to the loop containing L, Rz, C gives

$$L \frac{di_{L}(t)}{dt} + R_{2}i_{L}(t) = v_{c}(t) \rightarrow \frac{di_{L}(t)}{dt} = -\frac{R_{2}}{L}i_{L}(t) + L v_{c}(t)$$

Applying Kirchhoff's current law (KCL) at the junction of RI, Rz, C gives

$$C \frac{dv_{E}(t)}{dt} + L_{L}(t) = \underbrace{ett}_{E_{L}} - v_{E}(t) \xrightarrow{d} \frac{dv_{E}(t)}{dt} = -\frac{1}{c}L_{L}(t) - \frac{1}{e_{L}}c^{-e_{L}(t)} + L_{L}(e^{-e_{L}(t)}).$$

$$1-5$$

$$I \frac{d^{2}\theta(t)}{dt} = \lambda(t) - B \frac{d\theta tt}{dt} - \kappa \theta(t).$$
Letting  $x_{1}(t) \triangleq \theta(t)$ ,  $x_{2}(t) \triangleq \dot{\theta}(t)$ ,  $u(t) \triangleq \dot{\lambda}(t)$ 

$$\frac{d}{dt} \left( \theta(t) \right) = \dot{\theta}(t) \qquad \text{or} \qquad \dot{x}_{1}(t) = x_{2}(t)$$

$$\frac{d}{dt} \left( \dot{\theta}(t) \right) = -\frac{K}{T} \theta(t) - \frac{B}{T} \dot{\theta}(t) + \frac{1}{T} \lambda(t) \text{, or}$$

$$\dot{x}_{2}(t) = -\frac{K}{T} x_{1}(t) - \frac{B}{T} x_{2}(t) + \frac{1}{T} u(t).$$

$$\frac{dh_1(t)}{dt} = \frac{w_1(t)}{\alpha_1} + \frac{m(t)}{\alpha_1} - \frac{k}{\alpha_1} \left[ h_1(t) - h_2(t) \right]$$

$$\frac{dh_2(t)}{dt} = \frac{w_2(t)}{\alpha_2} + \frac{k}{\alpha_2} \left[ h_1(t) - h_2(t) \right]$$

$$(m(t) - w_1(t) k f_1(t) + w_2(t) f_2(t)$$

$$\frac{dv_1(t)}{dt} = \begin{cases} m(t) - \frac{v_1(t)k}{d_1h_1(t)} \left[h_1(t) - h_2(t)\right] & \text{for } h_1(t) \ge h_2(t) \\ m(t) + \frac{v_2(t)k}{d_2h_2(t)} \left[h_2(t) - h_1(t)\right] & \text{for } h_2(t) \ge h_1(t) \end{cases}$$

$$\frac{dv_{z}(t)}{dt} = \begin{cases} \frac{\mathcal{N}_{1}(t) k}{d_{1} h_{1}(t)} \left[ h_{1}(t) - h_{2}(t) \right] & \text{for } h_{1}(t) \ge h_{2}(t) \\ -\frac{\mathcal{N}_{2}(t) k}{d_{2} h_{2}(t)} \left[ h_{2}(t) - h_{1}(t) \right] & \text{for } h_{z}(t) \ge h_{1}(t) \end{cases}$$

$$\begin{aligned} \kappa_{a}e(t) &= R_{f}i_{f}(t) + l_{f}\frac{d}{dt}\left(i_{f}(t)\right) \\ \lambda(t) &= \kappa_{t}i_{f}(t) = I\frac{d\omega(t)}{dt} + B\omega(t) \\ \frac{di_{f}(t)}{dt} &= -\frac{R_{f}}{L_{f}}i_{f}(t) + \frac{\kappa_{a}}{L_{f}}e(t) \\ \frac{d\omega(t)}{dt} &= \frac{\kappa_{b}}{L_{f}}i_{f}(t) - \frac{B}{L_{f}}\omega(t) \end{aligned}.$$

Mass M<sub>1</sub>:  $f(t) = \kappa_2 y_1(t) + B_1 \hat{y}_1(t) + \kappa_1 [y_1(t) - y_2(t)] + B_2 [\hat{y}_1(t) - \hat{y}_2(t)] + M_1 \frac{d}{dt} (\hat{y}_1(t))$ 

Mass M2:  $0 = M_Z \frac{d}{dt} (\hat{y_z}(t)) + K_1 [y_z(t) - y_1(t)] + B_Z [\hat{y_z}(t) - \hat{y_t}(t)].$ 

Letting  $y_1(t), \dot{y}_1(t), y_2(t), \dot{y}_2(t)$  be the states we have

$$\frac{d}{dt}(y,(t)) = \hat{y},(t)$$

$$\begin{split} \frac{d}{dt}\left(\dot{y}_{i}(t)\right) &= -\frac{1}{M_{I}}\left[\kappa_{i} + \kappa_{z}\right]y_{i}(t) - \frac{\left[B_{i} + B_{z}\right]}{M_{I}}\dot{y}_{i}(t) + \frac{\kappa_{I}}{M_{I}}y_{z}(t) \\ &+ \frac{B_{z}}{M_{I}}\dot{y}_{z}(t) + \frac{1}{M_{I}}f(t) \end{split}$$

$$\frac{d}{dt}(y_2(t)) = \dot{y}_2(t)$$

$$\frac{d}{dt} \left( \mathring{y}_{2}(t) \right) = \frac{K_{1}}{M_{2}} y_{1}(t) + \frac{B_{2}}{M_{2}} \mathring{y}_{1}(t) - \frac{K_{1}}{M_{2}} y_{2}(t) - \frac{B_{2}}{M_{2}} \mathring{y}_{2}(t)$$

or, using x, \$ y, x2\$ y, x3\$ y2, x4\$ y2, u\$ f

$$\chi(t) = 
\begin{bmatrix}
0 & 1 & 0 & 0 \\
-[\kappa_{1}+\kappa_{2}] & -[\beta_{1}+\beta_{2}] & \kappa_{1} & \beta_{2} \\
M_{1} & M_{1} & M_{1} & M_{1}
\end{bmatrix}$$

$$\chi(t) = 
\begin{bmatrix}
0 & 0 & 0 & 1 \\
K_{1} & B_{2} & -\kappa_{1} & -B_{2} \\
M_{2} & M_{2} & M_{2} & M_{2}
\end{bmatrix}$$

$$+ 
\begin{bmatrix}
0 & 0 & 0 & 1 \\
M_{1} & M_{2} & M_{2} & M_{2}
\end{bmatrix}$$

$$+ 
\begin{bmatrix}
0 & 0 & 0 & 1 \\
M_{2} & M_{2} & M_{2}
\end{bmatrix}$$

$$+ 
\begin{bmatrix}
0 & 0 & 0 & 1 \\
M_{1} & M_{2} & M_{2}
\end{bmatrix}$$

1-9
Application of Kirchhoff's laws gives
$$c\frac{d}{dt}(v_c(t)) = i_{L_1}(t) + \frac{1}{N_c} i_{L_2}(t) + \frac{1}{N_c} i_{L_3}(t) + \frac{1}{N_c} i_{L_4}(t) + \frac{1}{N_c} i_{L_4}(t) + \frac{1}{N_c} i_{L_5}(t) + \frac{1}{N_c} i_{L$$

Letting No, i,, and i, be the states, algebraic manipulation of these equations gives

$$\begin{bmatrix}
\frac{d}{dt}(N_{c}(t)) \\
\frac{d}{dt}(i_{L_{1}}(t))
\end{bmatrix} = \begin{bmatrix}
0 & \frac{1}{C} & 0 \\
-\frac{L_{2}}{k^{2}} & -\frac{R_{1}L_{2}}{k^{2}} & \frac{MR_{2}}{k^{2}} \\
\frac{d}{dt}(i_{L_{2}}(t))
\end{bmatrix} \begin{bmatrix}
N_{c}(t) \\
\frac{d}{k^{2}} & \frac{MR_{1}}{k^{2}} & -\frac{R_{2}}{L_{2}} - \frac{M^{2}R_{2}}{L_{2}k^{2}} \\
\vdots \\
i_{L_{2}}(t)
\end{bmatrix}$$

+ 
$$\begin{bmatrix} 0 \\ \frac{L_2}{k^2} \\ -\frac{M}{k^2} \end{bmatrix}$$
 e(t), where  $k^2 = L_1 L_2 - M^2$ .

$$\frac{1-10}{R_{2}(t)i_{L}(t)+L} \frac{di_{L}(t)}{dt} = v_{c}(t)$$

$$-\frac{v_{c}(t)+c(t)}{R_{1}} = c \frac{dv_{c}(t)}{dt} + f(v_{c}(t))+i_{L}(t)$$

$$+ f(v_{c}(t))+i_{L}(t)$$

$$+ f(v_{c}(t))+i_{L}(t)$$

$$+ f(v_{c}(t))+i_{L}(t)$$

$$+ f(v_{c}(t))+i_{L}(t)$$

1-10 (continued)

$$\frac{di_{L}(t)}{dt} = -\frac{R_{2}(t)}{L} i_{L}(t) + \frac{1}{L} N_{c}(t) 
\frac{dN_{c}(t)}{dt} = -\frac{1}{C} i_{L}(t) - \frac{1}{R_{1}C} N_{c}(t) - \frac{f(N_{c}(t))}{C} 
+ \frac{1}{R_{1}C} e(t).$$

1 - 11

(i)  $\chi(t) = g(t, t_a) \chi(t_a)$ , let  $t_a = t$ , then  $\chi(t) = g(t, t) \chi(t)$ , which implies  $(\Rightarrow) g(t, t) = I$  for all t.

(ii) Consider the arbitrary times  $t_0,t_1,t_2$ , and the arbitrary states  $\chi(t_0),\chi(t_1),\chi(t_2)$ , then we have

 $\chi(t_1) = g(t_1, t_0) \chi(t_0)$ ,  $\chi(t_2) = \mathcal{L}(t_2, t_1) \chi(t_1)$ , and  $\chi(t_2) = \mathcal{Q}(t_2, t_0) \chi(t_0)$ . From the first two of these equations,

 $\chi(t_2) = \mathcal{L}(t_2, t_1) \chi(t_1) = \mathcal{L}(t_2, t_1) \mathcal{L}(t_1, t_0) \chi(t_0)$ but

 $x(t_2) = \mathcal{L}(t_2, t_0) x(t_0), there fore$ 

 $\mathcal{L}(t_2, t_0) = \mathcal{L}(t_2, t_1) \mathcal{L}(t_1, t_0)$  for all  $t_0, t_1, t_2$ . (III) From (II) with  $t_0 = t_2$ 

 $\mathcal{L}(t_2, t_2) = \mathcal{L}(t_2, t_1) \mathcal{L}(t_1, t_2) = \mathcal{I} \text{ from (i), so}$   $\mathcal{L}^{-1}(t_2, t_1) \mathcal{I} = \mathcal{L}^{-1}(t_2, t_1) = \mathcal{L}(t_1, t_2) \text{ for all } t_1, t_2.$ 

1-11 (cont.)

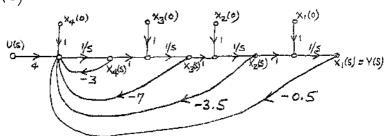

(iv) 
$$\chi(t) = \mathcal{L}(t, t_0) \chi(t_0)$$

$$\frac{d}{dt} \chi(t) = \dot{\chi}(t) = \mathcal{L}(t, t_0) \frac{d\chi(t_0)}{dt} + \left[\frac{d}{dt} \mathcal{L}(t, t_0)\right] \chi(t_0)$$
but  $\dot{\chi}(t) = \dot{\chi}(t) \chi(t)$ , so
$$\dot{\chi}(t) = \dot{\chi}(t, t_0) = \frac{d\mathcal{L}(t, t_0)}{dt} \chi(t_0) = \dot{\chi}(t) \mathcal{L}(t, t_0) \chi(t_0).$$
Since this holds for all  $\chi(t_0)$ ,
$$\frac{d\mathcal{L}(t, t_0)}{dt} = \dot{\chi}(t) \mathcal{L}(t, t_0).$$

$$\dot{x}_{1}(t) = x_{2}(t)$$
,  $\dot{x}_{2}(t) = x_{3}(t)$ ,  $\dot{x}_{3}(t) = -3x_{1}(t) - 6x_{2}(t) - 5x_{3}(t)$   
+10 u(t)

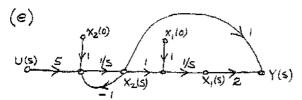

y(t) = x1(t).

(4)

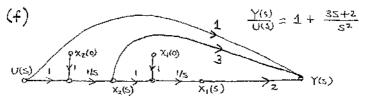

$$\dot{x}_{1}(t) = x_{2}(t), \quad \dot{x}_{2}(t) = x_{3}(t), \quad \dot{x}_{3}(t) = x_{4}(t),$$

 $\dot{x}_4(t) = -.5x_1(t) - 3.5x_2(t) - 7x_3(t) - 3x_4(t) + 4u(t),$  $y(t) = x_1(t).$ 

 $\dot{x}_{1}(t) = x_{2}(t)$ ,  $\dot{x}_{2}(t) = -x_{2}(t) + 5u(t)$ ,  $y(t) = 2x_{1}(t) + x_{2}(t)$ ; compare with part (a).

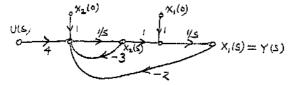

$$\dot{x}_1(t) = x_2(t)$$
,  $\dot{x}_2(t) = u(t)$ ,  $y(t) = 2x_1(t) + 3x_2(t) + u(t)$ .

compare with part (c).

$$\dot{x}_{1}(t) = x_{2}(t)$$
,  $\dot{x}_{2}(t) = x_{3}(t)$ ,  $\dot{x}_{3}(t) = -3x_{1}(t) - 6x_{2}(t) - 5x_{3}(t)$   
+ 104(t),

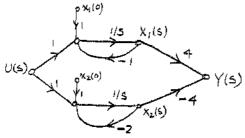

$$\dot{x}_{1}(t) = x_{2}(t)$$
,  $\dot{x}_{2}(t) = -2x_{1}(t) - 3x_{2}(t) + 4u(t)$ ,  
 $y(t) = x_{1}(t)$ .

Method 2: "canonical" or "de-coupled" form

$$Y(s) = \frac{4}{s+1} U(s) + \frac{-4}{s+2} U(s)$$

1-12 (h) (cont.)

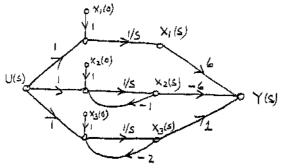

For this choice of state variables

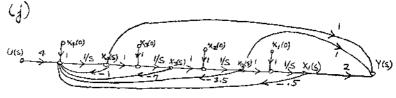

$$\dot{x}_{1}(t) = -x_{1}(t) + u(t), \ \dot{x}_{2}(t) = -2x_{2}(t) + u(t),$$

$$y(t) = 4x_{1}(t) - 4x_{2}(t).$$

(i) 
$$Y(s) = \begin{bmatrix} 6 \\ 5 \end{bmatrix} + \frac{-6}{5+1} + \frac{1}{5+2} \end{bmatrix} U(s)$$

 $\dot{x}_{1}(t) = u(t), \dot{x}_{2}(t) = -x_{2}(t) + u(t), \dot{x}_{3}(t) = -2x_{3}(t) + u(t),$   $y(t) = 6x_{1}(t) - 6x_{2}(t) + x_{3}(t).$ 

$$\dot{x}_{1}(t) = x_{2}(t), \dot{x}_{2}(t) = x_{3}(t), \dot{x}_{3}(t) = x_{4}(t),$$

$$\dot{x}_{4}(t) = -.5 \times, (t) -3.5 \times_{2}(t) -7 \times_{3}(t) - x_{4}(t) +4 u(t),$$

$$y(t) = 2x_{1}(t) + x_{2}(t) + x_{4}(t);$$

(b) 
$$\Phi(s) = \begin{bmatrix} \frac{1}{5} & \frac{1}{5^2} \\ 0 & \frac{1}{5} \end{bmatrix}$$
  $\varphi(t) = \begin{bmatrix} 1 & t \\ 0 & 1 \end{bmatrix}$ .

- (e)  $\Phi(s)$  and  $\varphi(t)$  are the same as in (a).
- (f) p(t) same as in part (b).

(h) 
$$\overline{\phi}(s) = \begin{bmatrix} \frac{1}{s+1} & 0 \\ 0 & \frac{1}{s+2} \end{bmatrix}$$
,  $\varphi(t) = \begin{bmatrix} e^{-t} & 0 \\ 0 & e^{-2t} \end{bmatrix}$ .

This solution applies for the canonical form of the state equations.

(i) The homogeneous part of each state equation is of the form  $\dot{x}_i(t) = a_i \times i(t)$ 

hence, the unforced solution has

 $\chi_{i}(t) = \epsilon^{a_{i}t} \chi_{i}(0)$  i = 1, 2, 3.

Therefore

$$\mathcal{L}(t) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & e^{-t} & 0 \\ 0 & 0 & e^{-2t} \end{bmatrix}.$$

1-14 £ and £ refer to the text defini(a) tions In Section 1.2.

$$\mathcal{E} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$
,  $\det (\mathcal{E}) \neq 0 \Rightarrow \text{ system } \frac{\text{cont rollable}}{\text{cont rollable}}$ .

$$G = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
,  $\det(G) \neq 0 \Rightarrow \text{system}$ 
observable.

$$U(s) \qquad \bigvee_{X_2(s)}^{X_2(s)} \qquad \bigvee_{X_1(s)=Y(s)}^{X_1(s)} \qquad X_1(s)=Y(s)$$

(b)  $E = same as in part (a) \Rightarrow controllable.$ 

$$G = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, det (G) = 0 \Rightarrow \underbrace{not observable}_{0}.$$

$$0 \Rightarrow \underbrace{x_{2}(0)}_{0} \qquad \underbrace{x_{1}(0)}_{0} \qquad \underbrace{x_{2}(0)}_{0} \qquad \underbrace{x_{2}(0)}_{0} \qquad \underbrace{x_{2}(0)}_{0} \qquad \underbrace{x_{3}(0)}_{0} \qquad \underbrace{x_{1}(0)}_{0} \qquad \underbrace{x_{2}(0)}_{0} \qquad \underbrace{x_{3}(0)}_{0} \qquad \underbrace{x_{4}(0)}_{0} \qquad \underbrace{x_{5}(0)}_{0} \qquad \underbrace{x_{5}(0)}_{0}$$

From the flowgraph, it is apparent that there is no way for  $x_1(t)$  to influence the output y(t).

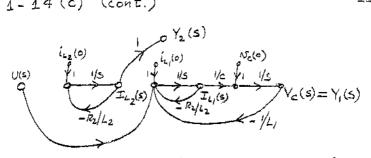

(c)
$$\stackrel{E}{=} \begin{bmatrix}
0 & \frac{1}{CL_1} & \frac{-R_1}{L_1^2C} \\
\frac{1}{L_1} & \frac{-R_1}{L_1^2} & \frac{R_1^2}{L_1^2} \\
0 & 0 & 0
\end{bmatrix}$$

$$\stackrel{\text{not controllable}}{=} \underbrace{\text{singular}}$$

$$G = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{C_1} & 0 \\ 0 & 1 & 0 & \frac{-R_2}{L_2} \end{bmatrix}.$$

The matrix formed by taking the first 3 columns is nonsingular; therefore & has rank 3 and the system is observable.

#### 1-14 (c) (cont.)

clearly, the control cannot influence in (t).

$$A = \begin{bmatrix} 0 & 2 & 0 \\ -2 & -4 & 2 \\ 2 & 4 & -4 \end{bmatrix} \qquad b = \begin{bmatrix} 0 \\ 2 \\ -2 \end{bmatrix}$$

$$E = \begin{bmatrix} 0 & 4 & -24 \\ 2 & -12 & 72 \\ -2 & 16 & -104 \end{bmatrix}$$
 det  $(E) \neq 0 \Rightarrow$  system controllable.

$$G = \begin{bmatrix} 1 & 0 & -4 \\ 0 & 2 & -8 \\ 0 & 0 & 4 \end{bmatrix}, det(G) \neq 0 \Rightarrow$$

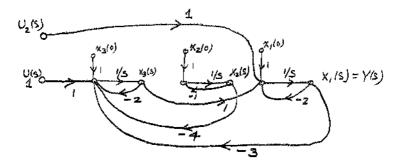

$$\begin{array}{c} \text{system observable} \\ \text{outs} \\ \text{outs$$

$$1-14 (e)$$

$$E = \begin{bmatrix} 0 & 1 & 1 & -2 & -4 & 1 \\ 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & -2 & -3 & 1 & 12 \end{bmatrix}.$$

By inspection, the rank of E is 2; therefore, the system is not controllable

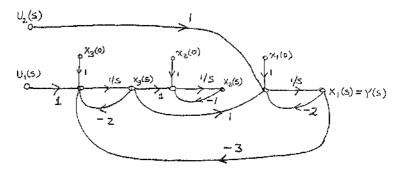

$$\mathcal{G} = \begin{bmatrix} 1 & -2 & 1 \\ 0 & 0 & -4 \\ 0 & 1 & -4 \end{bmatrix}, Nonsingular \Rightarrow Observable.$$

$$\mathcal{E} = \begin{bmatrix}
0 & 1 & 1 & -2 & -4 & 1 \\
0 & 0 & 1 & 0 & -3 & -3 \\
1 & 0 & -2 & -3 & 1 & 12
\end{bmatrix}.$$

The 3x3 submatrix consisting of the first 3 rows and columns is nonsingular; there fore, the rank is 3, and the system is controllable.

$$G = \begin{bmatrix} 1 & -2 & 1 \\ 0 & 0 & 0 \\ 0 & 1 & -4 \end{bmatrix} \leftarrow \begin{array}{c} 17 \\ \text{singular} \Rightarrow \\ \text{not observable} \end{array}$$

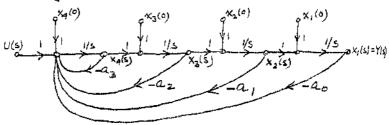

Expanding the determinant by minors according to the elements of the first column yields

$$det(E) = 1 \implies \underbrace{controllable}_{\text{controllable}} \text{ for all } \underbrace{a_0, a_1, a_2, a_3}_{\text{controllable}}.$$

$$G = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix}, \text{ nonsingular} \implies \underbrace{observable}_{\text{for all } a_0, a_1, a_2, a_3}.$$

1-14 (g) (cont.)

1-15
The system given in this problem is in the canonical, or normal, form. In the article "Controllability and Observability in Multivariable Control Systems", by E.G. Gilbert, in the Journal of the society for Industrial and Applied Mathematics (SIAM), Series A, Vol. 1, No. 2, 1963, the definitions of controllability and observability are given in terms of a system in this canonic form.
The definitions are:

- 1) The system [defined in Example 1-15] is controllable if k has no zero rows, i.e.,  $k \neq 0$ , k = 1, 2, 3, 4.
- a) The system [defined in Example 1-15] is observable if the matrix  $C = [c, c_2 c_3 c_4]$  has no zero columns, i.e.,  $ci \neq 0$ , i = 1, 2, 3, 4.

1-15 (cont.)

If the E matrix is formed  $E = \begin{bmatrix} b_1 & \lambda_1 b_1 & \lambda_1^2 b_1 & \lambda_1^3 b_1 \\ b_2 & \lambda_2 b_2 & \lambda_2^2 b_2 & \lambda_3^3 b_3 \\ b_3 & \lambda_3 b_3 & \lambda_3^2 b_3 & \lambda_3^3 b_3 \\ b_4 & \lambda_4 b_4 & \lambda_4^2 b_4 & \lambda_4^3 b_4 \end{bmatrix}$ 

it is readily seen that if any of the bi's is zero, a row of Eis zero, hence E is singular. Also note that if the eigenvalues are not all distinct -- as assumed -- then the matrix E is again singular because two or more rows are linearly dependent.

similar observations apply to the matrix &, which has the same form as £, but with a replacing bi.

#### CHAPTER 2

NOTE: Since none of the problems here require numerical answers, we have not introduced conversion factors to account for the physical units used.

2-1
$$(a) J = \int_0^1 \left[ N_2(t) - M \right]^2 dt, \text{ or}$$

$$J = \int_0^1 \left[ N_2(t) - M \right] dt.$$

(b) state constraints:

(i)  $0 \le h_1(t) \le H_{1 \max}$  and  $H_{2 \max}$  are the depths  $0 \le h_2(t) \le H_{2 \max}$  of the tanks

(ii)  $0 \le v_1(t) \le V_{1max}$   $\begin{cases} V_{1max} \text{ and } V_{2max} \\ \text{are the capacities} \end{cases}$  of the tanks.

Notice that Vimax = a, Himax)

 $V_{2max} = d_2 H_{2max}$ , and that satisfaction of the constraints (i) implies satisfaction of the constraints (ii) and vice-versa; therefore, satisfaction of (i) or (ii) for all  $t \in [0, 1]$  is sufficient.

$$0 \le w_1(t) \le w_{max}$$
 $0 \le m(t) \le M_{max}$  for all determined by  $0 \le w_2(t) \le w_{2max}$  te[0, ] maximum flow rates.

2-2

The minus sign converts the maximization problem to a minimization problem.

(b) same as 2-1, but with the additional control constraint  $\int_0^{1 day} \int_0^{1 day} dt \leq N.$ 

2-3

(a) Letting if (t) and W(t) be the states, the state equations are

$$\frac{di_{f}(t)}{dt} = -\frac{R_{f}}{L_{f}}i_{f}(t) + \frac{1}{L_{f}}e(t)$$

$$\frac{d\omega(t)}{dt} = \frac{\kappa_t}{\pi} i_f(t) - \frac{B}{T} \omega(t) - \frac{1}{T} \lambda_L(t).$$

(b) state constraints

| if(t) | ≤ I fmax Protection against over heating.

| w(t) | & 12 max

speed limit corresponding to no load -  $\lambda_{L}(t) = 0$ .

Control constraints:

e(t) | E E max

voltage limitation on regulator.

 $|\lambda_L(t)| \leq \lambda_{\max}$ 

slope limitation on hills that can be safely climbed by the vehicle.

(c) (i) Power supplied by voltage regulating system proportional to e2(t):

$$J = \int_0^{t} \left[ \overline{k} \omega(t) - 5 \right]^2 + \mu e^2(t) dt.$$

M is a weighting factor, k is inserted to illustrate a conversion factor.

(ii) Power supplied by voltage regulating system is equal to extripte):

$$J = \int_0^{\epsilon_f} \left[ \left[ k \omega(t) - 5 \right]^2 + \mu \, e(t) \, i_f(t) \right] dt.$$

M is a weighting factor.

2-4

(a) State constraints:

 $14.9^{\circ} \leq \theta(30) \leq 15.1^{\circ}$  end point constraint.

control constraints:

lu(t) | = Umax limited thrust available.

2-4 (cont.)
(b) 
$$J = \int_{0}^{30} |u(t)| dt$$
.

Rate of fuel expenditure is proportional to lult).

2-5

(a) State constraints:  

$$14.9^{\circ} \leq \theta(t_f) \leq 15.1^{\circ}$$

Control constraints:

|ult) | & Umax

There might also be a constraint on the total amount of fuel available to perform the maneuver if so, this constraint would be

$$\int_{0}^{t} |u(t)| dt \leq M,$$

where M is a specified real number

(b) 
$$J = \int_{0}^{t_{f}} dt$$
  $t_{f}$  is free --

the first time the constraint

is satisfied.  $\Theta(t_f) \leq 15.1^\circ$ 

2-6

(a) (Inherent physical) constraints: State --  $0 \le x_1(t)$  assuming surface of the earth at zero elevation and a 2-6 (cont.) flat earth approximation.

Mmin ≤ x5(t) ≤ m(to); this is a fuel-expended constraint and could alternatively be expressed in terms of an integral involving the thrust.

control -- -  $TT \le U_2(t) \le TT$ limation on thrust angle  $0 \le U_1(t) \le T_{max}$ .

(b)  $J = -\chi(t_f)$  (J to be minimized). An additional state constraint imposed by the problem statement is  $\chi(t_f) = \chi_3(t_f) = 3$  miles.

(c)  $J = \int_0^{2.5} u_1(t) dt$ , or  $J = -x_5(t_f)$ .

Additional state constraints imposed:  $x_i(t_f) = 500 \text{ miles}$  $x_3(t_f) = 3 \text{ miles}$ .

#### CHAPTER 3

3-1
(a) 
$$x_{1}(t+\Delta t) \approx x_{1}(t) + \Delta t \times_{2}(t)$$

$$x_{2}(t+\Delta t) \approx x_{2}(t) + \Delta t \left[-x_{1}(t) + \left[1-x_{1}^{2}(t)\right]x_{2}(t)\right] + \Delta t \text{ U(t)}.$$
Collecting terms and defining  $x_{1}(t) = x_{1}(k)$ 

$$x_{2}(t) = x_{2}(k), x_{1}(t+\Delta t) = x_{1}(k+1), \text{ etc.}$$

$$x_{1}(k+1) = x_{1}(k) + 0.01 \times_{2}(k)$$

$$x_{2}(k+1) = -0.01 \times_{1}(k) + \left[1. + 0.01 \right]_{1} - x_{1}^{2}(k)$$

$$+0.01 \text{ U(k)}$$

$$J = \left[ x_{1}(\tau) - 5 \right]^{2} + \int_{0}^{N\Delta t} \left[ x_{2}^{2}(t) + 20 \left[ x_{1}(t) - 5 \right]^{2} + u^{2}(t) \right] dt$$

$$= \left[ x_{1}(\tau) - 5 \right]^{2} + \int_{0}^{\Delta t} \left[ dt + \int_{\Delta t}^{2\Delta t} dt + \int_{\Delta t}^{N\Delta t} dt \right] dt + \int_{N-\Omega \Delta t}^{N\Delta t} dt$$

$$= \left[ x_{1}(N) - 5 \right]^{2} + 0.01 \sum_{k=0}^{N-1} \left\{ x_{2}^{2}(k) + 20 \left[ x_{1}(k) - 5 \right]^{2} + u^{2}(k) \right\}_{1}^{2}$$

N= 10/0.01 = 1000.

b. No computational adjustments required.

Following the procedure outlined in Section 3.7, we begin with a zerostage process.

State value X(2)	"Minimum" Cost $J_{2,2}^*(x(2)) =  x(2) $
.2	. 2.
.	• [
0.	0.
1	-1
2	.2

Next, consider a one-stage process with  $J_{1,2}^*(\chi(1)) = \min_{u(1)} \left\{ |\chi(1)| + J_{2,2}^*(\chi(2)) \right\}$ .

The trial control values are u(1) = -1, o., +.1.

State Value X(1)	Control value u(1)	Next State X(2)	Cost $C_{1,2}^{*}(x(1),u(1))$ $= x(1) +J_{2,2}^{*}(x(2))$	Min. Cost J <sub>U2</sub> (K(II)	opt, control u*(xci);)
	1	2	( • 2 ) • 4

1.0	.4 .2 0. 2 4	1,0 1,0 1,4 1,2	$ \begin{pmatrix} .4 \\ .2 \\ 0. \\ .2 \\ .2 \\ .4 \end{pmatrix} $ $ \begin{pmatrix} 1.2 \\ .80 \\ .5L \\ .32 \\ .452 \end{pmatrix} $ $ .56$	,52	~, Z.

(b) 
$$\chi(0) = 1.0 \rightarrow u*(1.0,0) = -.2 \rightarrow \chi(1) = 0.4$$
  
 $\rightarrow u*(0.4,1) = -.32$  (using linear interpolation)

First, we consider a zero-stage process. If the point X(2) does not lie in the target set, we assign a very large cost, say  $10^{25}$ , to this point.

State Value X(2)	Cost J* (x(z))
6.0	1025
4,0	1025
4.0	0.
0,0	٥.

Next, consider a 1-stage process with  $J_{1,2}^*(x(1)) = U^2(1)$ . Looking at the state equations, it is apparent that positive control values will move the system away from the target set and add to the cost; therefore, only non-positive values of control will be tried. Of course, if a computer were being used, it might be just as well to include the positive control values, rather than complicate the programming required.

State value X(1)	Control value u(1)	Next State X(2)	Min cost assuming u(1) applied  (*) (X(1), U(1))	Min. Cost J <sub>b2</sub> (x(1))	0pt. Control u*(x(),1)

0,0	0,0 5 -1.0	0.0 NA NA	$ \begin{cases} 0. \\ - \end{cases} + \begin{cases} 0. \\ - \end{cases} = 0, $	ο,	0.

Next, we calculate I\* (x(0))

X(o)	u(o)	<b>%</b> (i)	Co,z (x(0), U(0))	J <sub>0,2</sub> (x(0))	u*(x(0),0)
6.0	0,0 5 -1.0	4.5(M) 4.0 3.5	(-) -25 1.   1, =1.25 1.75	1,25	~·5¯
4.0	0.0 5 -1.0	3.0 2.5 2.0	$ \begin{pmatrix} 0, \\ .25 \\ 1. \end{pmatrix} + \begin{pmatrix} .5 \\ .25 \\ 0. \end{pmatrix} = .5 $	,5	0.0r - 5
2.0	0.0 - ,5 -1,0	1.5 6.5	$ \begin{pmatrix} 0, \\ .25 \\ 1, \end{pmatrix} + \begin{pmatrix} 0, \\ 0, \\ 0, \end{pmatrix} = .25 $ 1.	O.	0.
0.0	0.0 5 1.0	0. NA NA	$\begin{cases} 0, \\ .25 \\ 1, \end{cases} + \begin{cases} 0, \\ - \\ - \end{cases} = -$	0,	0.

$$\chi(0) = 6. \longrightarrow u^*(6,0) = -.5 \longrightarrow \chi(1) = 4.0$$
  
 $\longrightarrow u^*(4.0,1) = -1. \longrightarrow \chi(2) = 2.0.$ 

3-6

In this problem solution we will illustrate that consideration of a zero-stage process is simply a computational convenience. This will be done by using an alternative approach. Let  $T_{1,2}^*(\chi(1)) = \min\{2 \mid \chi(2) - .4 \mid + \mid u(1) \mid\}$ .

<b>x</b> (1)	u(I)	X(2)	C# (x(1), 14(1))		U*(*(1)1)

Note 1: Notice that the state value x(0) is not included in the performance measure; however, if it was, only the minimum costs, not the optimal control law, would be altered.

Note 2: If the "standard" approach had been used in the solution, the only difference would have been in the intermediate costs;

Jo,2 (x(0)) and the optimal control law would be as found above.

(b) 
$$\chi(0) = .2 \rightarrow (L^{*}(.2,0) = 0, \rightarrow \chi(1) = .2$$
  
 $\rightarrow L^{*}(.2,1) = .2 \rightarrow \chi(2) = .4$ .

$$\mathcal{H} = \frac{1}{2} \left[ g_1 x_1^2(t) + g_2 x_2^2(t) + u^2(t) \right] + \frac{\partial J^*}{\partial x_1} (x_1 u_1 t) x_2(t)$$

$$+\frac{\partial J^*}{\partial x_2}(x(t),t)\left[-x_1(t)+x_2(t)+u(t)\right]$$

is to be minimized with respect to u(t) for all  $t \in [0,T]$  and u(t) satisfying  $|u(t)| \le 1$ . The terms in )t involving u(t) are  $\frac{1}{2}u^2(t) + \frac{3}{2}\pi/2x_2 \cdot u(t)$ ; therefore, for |u(t)| < 1

$$\frac{\partial}{\partial u} \left[ \frac{1}{2} u^2(t) + \frac{\partial J^*}{\partial x_2} u(t) \right] \stackrel{\text{Must}}{=} 0$$
.

Solving this for ult) gives

$$u^*(t) = -J_{\kappa_2}^*(x(t),t).$$

Since |u\*(t)| < 1, this is valid for  $|J_{x_2}^*| < 1$ .

If  $J_{x_2}^* \ge 1$ , is minimized with respect

to u(t) by  $u^*(t) = -1$ ; for  $J_x^* \le -1$ ,  $u^*(t) = +1$  is the minimizing choice. In summary,

$$u^{*}(t) = \begin{cases} -1 & J_{x_{2}}^{*}(\chi(t), t) > 1 \\ -J_{x_{2}}^{*}(\chi(t), t) & |J_{x_{2}}^{*}(\chi(t), t)| \leq 1 \\ +1 & J_{x_{2}}^{*}(\chi(t), t) < -1 \end{cases}$$

3-8

)  $(=\frac{1}{4}x^{2}(t)+\frac{1}{2}u^{2}(t)+J_{x}^{*}(x(t),t)\cdot[-10x(t)+u(t)].$ Minimization with respect to u(t) gives

$$\frac{\partial \mathcal{H}}{\partial u} \stackrel{\text{set}}{=} 0 = u^*(t) + J_x^*(x(t),t) \Rightarrow u^*(t) = -J_x^*(x(t),t)$$
therefore, the H-J-B Equation is (omitting the arguments of J\*)
$$J_x^* + \frac{1}{4} x^2 + \frac{1}{2} \left[ J_x^* \right]^2 - 10 x J_x^* - \left[ J_x^* \right]^2 = 0.$$
Guessing a solution of the form  $J^* = \frac{1}{2} K(t) x^4 t$  (since this is a linear regulator problem) gives

Je" = 生 K(t) x2(t) , Jx" = K(t) x(t), which when substituted into the H-J-B Eq. yields

 $\frac{1}{2} \tilde{K}(t) \chi^{2}(t) - \frac{1}{2} K^{2}(t) \chi^{2}(t) - \frac{1}{4} \chi^{2}(t) - 10K(t) \chi^{2}(t) = 0$ 

Since this must be satisfied for all xtt)  $\dot{K}(t) - K^{2}(t) + \frac{1}{2} - 20K(t) = 0$ 

Separating variables and solving gives  $\frac{1}{\sqrt{402}} \log_{\epsilon} \left[ \frac{2\kappa(t) + 20 - \sqrt{402}}{2\kappa(t) + 20 + \sqrt{402}} \right] = t + c,$ 

c, is a constant of integration. From Eq. (3.12-15) the boundary condition is K(0.04) = 1. Solving for c, leads to the

$$K(t) = \frac{0.421 + 0.025 e^{-1401} t}{-0.021 + e^{-1402} t}$$

and  $U*(t) = K(t) \times (t)$ .

3-11 Augment the original state equations by

defining  $x_{n+1}(t) = \int_{-1}^{t_p} u^2(t) dt + x_{n+1}(t_0)$  and let Kn+1(to) be zero. The (n+1) st state equation then is

 $\dot{x}_{n+1}(t) = u^2(t)$ ,  $x_{n+1}(t_0) = 0$ .

Solve the original problem with the additional state included and the constraint

0 \( \times\_{n+1}(t) \) \( \times\_{n} \) for all \( t \in [t\_0 t\_4] \).

3 - 12

(a) An appropriate recurrence equation is  $c_{ig}^{(k+i)} = \min_{\substack{\ell \\ \ell \neq i}} \left\{ c_{i\ell}^{(0)} + c_{\ell j}^{(k)} \right\}.$ 

(b) 
$$c_{ab}^{(1)} = min \left\{ 1+0,5+6,10+3,2+9 \right\} = 1$$
 $c_{ac}^{(1)} = min \left\{ 1+6,5+6,10+2,2+15 \right\} = 5$ 
 $c_{ad}^{(1)} = min \left\{ 1+3,5+2,10+0,2+4 \right\} = 4$ 
 $c_{ae}^{(1)} = min \left\{ 1+9,5+15,10+4,2+0 \right\} = 2$ 
 $c_{ba}^{(1)} = c_{ab}^{(1)} \quad \text{by symmetry}$ 
 $c_{bc}^{(1)} = min \left\{ 1+5,6+0,3+2,9+15 \right\} = 5$ 
 $c_{bd}^{(1)} = min \left\{ 1+10,6+2,3+0,9+4 \right\} = 3$ 
 $c_{be}^{(1)} = min \left\{ 1+2,6+15,3+4,9+0 \right\} = 3$ 
 $c_{ca}^{(1)} = c_{ac}^{(1)}, c_{cb}^{(1)} = c_{bc}^{(1)} \quad \text{by symmetry}}$ 
 $c_{cd}^{(2)} = min \left\{ 5+10,6+3,2+0,15+4 \right\} = 2$ 

$$c_{ce}^{(1)} = \min \left\{ 5 + 2, 6 + 9, 2 + 4, 15 + 0 \right\} = 6$$

$$c_{da}^{(1)} = c_{ad}^{(1)}, c_{db}^{(1)} = c_{bd}^{(1)}, c_{dc}^{(1)} = c_{cd}^{(1)} \quad \text{by symmetry}$$

$$c_{de}^{(1)} = \min \left\{ 10 + 2, 3 + 9, 2 + 15, 4 + 0 \right\} = 4$$

$$c_{de}^{(1)} = \min \left\{ 10 + 2, 3 + 9, 2 + 15, 4 + 0 \right\} = 4$$

$$c_{de}^{(1)} = \begin{bmatrix} 0 & 1 & 5 & 4 & 2 \\ 1 & 0 & 5 & 3 & 3 \\ 5 & 5 & 0 & 2 & 6 \\ 4 & 3 & 2 & 0 & 4 \\ 2 & 3 & 6 & 4 & 0 \end{bmatrix} c$$

Next, find & (2):  $c_{ab}^{(2)} = \min \left\{ 1 + 0, 5 + 5, 10 + 3, 2 + 3 \right\} = 1$  $c_{ac}^{(2)} = \min \{1+5, 5+0, 10+2, 2+6\} = 5$ cad = min {1+3,5+2,10+0,2+4} = 4  $c_{ae}^{(2)} = \min \{1+3,5+6,10+4,2+0\} = 2$  $c_{ba}^{(2)} = c_{ab}^{(2)}$ cb2 = min { 1+5,6+0,3+2,9+6} = 5  $c_{bd}^{(2)} = \min\{1+4, 6+2, 3+0, 9+4\} = 3$  $c_{be}^{(2)} = \min \{1+2,6+6,3+4,9+0\} = 3$  $C_{ca}^{(2)} = C_{ac}^{(2)}, C_{cb}^{(2)} = C_{bc}^{(2)}$ cod = min {5+4, 6+3,2+0, 15+4} = 2  $C_{ca}^{(2)} = \min \{ 5+2, 6+3, 2+4, 15+0 \} = 6$  $c_{da}^{(2)} = c_{ad}^{(2)}, c_{db}^{(2)} = c_{bd}^{(2)}, c_{dc}^{(2)} = c_{cd}^{(2)}$  $c_{de}^{(2)} = \min\{10+2,3+3,2+6,4+0\} = 4$ 

$$C^{(2)} = \begin{bmatrix} 0 & 1 & 5 & 4 & 2 \\ 0 & 1 & 5 & 4 & 2 \\ 1 & 0 & 5 & 3 & 3 \\ 5 & 5 & 0 & 2 & 6 \\ 4 & 3 & 2 & 0 & 4 \\ 2 & 3 & 6 & 4 & 0 \end{bmatrix} e$$

Comparing  $S^{(1)}$  and  $S^{(2)}$  element by element we see that  $S^{(2)} = S^{(2)}$ , hence all optimal paths pass through at most one intermediate node.

- (c) Since  $\mathcal{L}^{(2)} = \mathcal{L}^{(1)}$  the optimal paths are not improved by allowing the possibility of additional nodes.
- (d)  $c_{ij}^{(k+1)} \le c_{ij}^{(k)}$  for all i, j = j, 2, ..., 4 and for all k = 0, 1, 2.
- (e) Essentially the same procedure is followed, but the below-diagonal elements of C(4) would also have to be computed.

In part (b), another matrix containing information sufficient to generate the optimal routes would usually be stored. In this case, the appropriate matrix, which we shall designate by P, is

The 13th element of P is the first 41 node on the optimal path from i to 3 which is encountered after leaving i. For example, the optimal path from a to d begins by moving from a to b. To find the sequence of nodes on the optimal path between any two nodes we use P and the principle of optimality. For example, the optimal path from a to d begins by going to b. If the path a-b-2-2-d is to be optimal, then the segment b-?-?-d must be optimal. Looking at P we see that the optimal path from b to d is to go directly from b tod, hence, a-b-d is the optimal path from a to d.

3-13
(a) J,\*(w) ≜ w, v, , w, ≤ w.

$$J_{2}^{*}(W) = \max_{w_{1}, w_{2} \geq 0} \left\{ w_{2}, v_{2} + w_{1}, v_{1} \right\}$$

$$w_{1} + w_{2} \leq W$$

$$= \max_{w_{1}, w_{2}} \max_{w_{2}, w_{3}} \left\{ w_{2} + w_{1}, v_{2} \right\}$$

$$= \max_{0 \le w_2 \le w} \max_{0 \le w_1 \le w - w_2} \left\{ w_1 v_2 + w_1 v_1 \right\}$$

$$= \max_{0 \le w_2 \le w} \left\{ w_2 v_2 + \max_{0 \le w_1 \le w - w_2} \left[ w_1 v_1 \right] \right\}$$

$$J_{3}^{*}(W) = \max_{\substack{M_{1}, M_{2}, M_{3} \geq 0 \\ M_{1}, M_{2}, M_{3} \geq 0}} \left\{ w_{3} v_{3} + \omega_{2} v_{2} + w_{1} v_{1} \right\}$$

$$= \max_{\substack{0 \leq w_{3} \leq W}} \left\{ w_{3} v_{3} + \max_{\substack{M_{1} w_{2} \leq W = w_{3} \\ W_{1} + w_{1} \leq W - w_{2}}} \left[ w_{2} v_{2} + w_{1} v_{1} \right] \right\}$$

$$= \max_{\substack{0 \leq w_{3} \leq W}} \left\{ w_{3} v_{3} + J_{2}^{*} (W - W_{3}) \right\},$$

etc.

(b) In carrying out the computations for the three-activity process, we must allow the argument of Ji\* to be a variable -- at least for i=1,2 -- in the range [0, w], where w=11,000 lb.

Let automobiles be activity no. 1:

$$J_1^*(\alpha) = 0$$
, for  $0 \le \alpha < 4000$   
= 3000,  $4000 \le \alpha < 8000$ 

Let refrigerators be activity no. 2:

$$J_{2}^{*}(d) = \max_{0 \le w_{2} \le w} \left\{ w_{2} v_{2} + J_{1}^{*}(\alpha - w_{2}) \right\}$$

$$= \left[ \frac{d}{400} \right] \cdot 180 \quad \text{for} \quad 0 \le \alpha < 4000$$

$$= 3000 + \left[ \frac{\alpha - 4000}{400} \right] \cdot 280 \quad 4000 \le \alpha < 8000$$

= 6000 + \[ \frac{d-8000}{400} \]. 280 \, 8000 \leq d \leq 11,000, where x means the largest integer less than, or equal to, x.

Let sinks be activity no. 3, the maximization can be performed by looking at

max 0≤w, ≤11, ωο { w3v3 + J2\* (1, ωο-w3)} for a few "critical" values of wa, with

J3\*(11,000) = \$8060, W3 = 200 => W2 = 2800 , W1 = 8000.

$$J_{2}^{*}(d) = \begin{bmatrix} \frac{d}{400} \\ \frac{1}{400} \end{bmatrix} \cdot 280 \quad 0 \le d < 4000$$

$$= 3000 + \begin{bmatrix} \frac{d}{400} \\ \frac{1}{400} \end{bmatrix} \cdot 280 \quad 4000 \le d < 8000$$

$$= 5800 + \begin{bmatrix} \frac{d}{400} \\ \frac{1}{400} \end{bmatrix} \cdot 250 \quad 8000 \le d \le 11,000.$$

Note: I car + 10 refrig. better than 2 cars.

44

Again, by inspecting a few critical values Jz\*(W) is found:

$$J_3^*(11,000) = $7650$$
 and value  $W_1 = 4000$  \$3000  $W_2 = 6800$  \$4550  $W_3 = 200$  \$100 \$7650

3-14

A sampling of the results found is tabulated below. The definitions used were

$$J_{N-l,N}^{*}(x(N-1)) = \min_{u(N-1)} \left\{ x^{2}(N) + \lambda \Delta t \ u^{2}(N-1) \right\}$$

$$J_{N-l,N}^{*}(x(N-1)) = \min_{u(N-1)} \left\{ x^{2}(N) + \lambda \Delta t \ u^{2}(N-1) \right\}$$

$$J_{N-K,N}^*\left(\chi(N-K)\right)=\min_{u(N-K)}\left\{\lambda \Delta t \ u^2(N-K)+J_{N-K+j,N}^*\left(\chi(N-K+j)\right)\right\}.$$

			131	
X(k)	J* (x(0))	u*(xω),σ)	J*(x(1))	u*(x(1),1)
3.0	0.314	-0.34	1,140	-1.00
2,5	0.218	-0.30	0.750	-1.00
2.0	0.139	-0.24	0.480	-0.80
1.5	0.079	-0.18	0.270	-0.60
1.0	0.035	-0.12.	0.120	-0.40
0.5	0,009	-0.06	0.030	-0.20
0,0	0.000	0,00	0.000	0.60

Defining a performance measure

 $J = \chi^{2}(I),$ 

which will be zero if x(1)=0 and positive otherwise, we find

χ(o)	J*, (x(0))	u*(x(0),0)
3.0	4.000	
2.5	2.250	***
2.0	1.000	
1.5	0.250	
1.0	0.000	-/,00
0.5	0.000	- 0.50
0.0	0.000	6,00

of course this problem can be worked by inspection.

## 3-19

The optimal control sequences and the resulting final states for various values of  $\lambda$  are shown below.

λ	u*(o)	u*(1)	X(2)
0.5	-0.60	- 0.60	0.30
2.0	-0.38	-0.38	0.74
4.0	-0.24	-0.26	1.00

- (a) As λ increases indicating more concern over control effort the control magnitudes decrease.
- (b) As a increases the increased premium on control effort causes less concern for the final state

3-19 (6) (cont.) value, hence the magnifule of x(2)increases.

## 3-20

3-20						
a	J * 2	u*(0)	u*(1)	×(2)		
0.0	1,125	-0.38	- 0.38	0.74		
-0.4	0.174	-0.10	0.16	0-32		

- (a) With a = -0.4 the system moves toward the origin (the desired state) even with no control applied. Thus, the system is easier to control the final state is closer to zero with less expenditure of control effort.
- (b) with a = 0.4 the system difference equation is  $\chi(k+1) = 1.4 \chi(k) + u(k).$

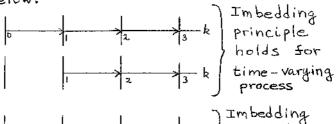

This system is unstable and will move away from the origin if no control is applied. The cost of controlling this system will be greater than for a = 0. or a = -0.4 and the final value of x should be greater with a = 0.4.

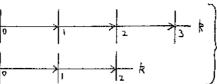

3-21 (a)  $u^*(0) = -0.5 \rightarrow x(1) = 2.0 \rightarrow u^*(1) = -0.5 \rightarrow$  $\chi(z) = 1.5 \rightarrow U*(z) = -0.5 \rightarrow \chi(3) = 1.0$ J# (2.5) = 2.5.

(b) U\*(0) = -0.5 → X(1) should be 2.0, but actually is 2,1 -> u\*(1) = -0,52 -> x(2)=1.58 -> u\*(2)=-0.52 -> x(3)=1.06.

(a) The optimal controls and minimum costs for the final two stages of the three-stage process in 3-14(b) are identical with those of the two-stage process in 3-14 (a) ; hence, the solution of 3-14(a) is contained, or "imbedded" in the solution of 3-14 (6).

(b) Only if certain conditions are met. For example, the solution of a twostage process beginning at k=1 is imbedded in the solution of a three-stage process beginning at k=0, as indicated by the sketches below.

Imbedding
principle
doesn't hold
for time-varying
process

## CHAPTER 4

4-1

This theorem can be proved by following the argument used in proving the fundamental theorem of the calculus of variations in section 4.1.

4-2

Suppose that h(t) is non-zero, say positive, at some point in the interval [to,tq]. Since h is a continuous function, then there exists an interval [t,tz] contained in [to,tq] in which h is positive. Let us select.

Let us select  $5x(t) = \begin{cases} (t-t_1)(t_2-t) & \text{for } t \in [t_1, t_2] \\ 0 & \text{for other} \\ t \in [t_0, t_4]. \end{cases}$ 

Clearly this choice for 8x is a continuous function. Now, for this choice of 8x

 $\int_{t_0}^{t_f} h(t) \, S x(t) \, dt = \int_{t_i}^{t_z} h(t) \, S x(t) \, dt$ 

which is positive because the integrand of the right side is always positive, except at to and ti, where it is zero. Thus, if hit

is not identically zero in [to,ti], then

\int\_t^{t\_f} h(t) \( \text{Sx(t)} \) dt

will not be zero for all continuous functions 8%.

4-3
(a) 
$$f(t+\Delta t)-f(t) = 4(t+\Delta t)^3 + \frac{5}{t+\Delta t}$$

$$-4t^3 - 5/t$$

$$\frac{(t+\Delta t)^3}{t+\Delta t} = \frac{5}{t} \cdot \frac{1}{1+\frac{\Delta t}{2}} = \frac{5}{t} \left[ 1 - \frac{\Delta t}{t} + \frac{(\Delta t)^2}{t^2} - \dots \right]$$

:. 
$$f(t+\Delta t) - f(t) = 12 t^2 \Delta t + 12 t (\Delta t)^2 + 4(\Delta t)^3 - 5\Delta t / t^2 + \cdots$$

Separating terms that are linear in  $\Delta t$  df(t,  $\Delta t$ ) =  $\left[12t^2 - 5/t^2\right] \Delta t$ .

(b) 
$$f(g+\Delta g)-f(g)=5[g_1+\Delta g_1]^2$$
  
  $+6[g_1+\Delta g_1][g_2+\Delta g_2]+2[g_2+\Delta g_2]^2$   
  $-5g_1^2-6g_1g_2-2g_2^2$ 

$$= 5 \left[ g_1^2 + 2g_1 \Delta g_1 + (\Delta g_1)^2 \right] + 6 \left[ g_1 g_2 + g_2 \Delta g_1 + g_1 \Delta g_1 + 2 \left[ g_2^2 + 2g_2 \Delta g_2 + (\Delta g_2)^2 \right] - 5 g_1^2 - 6 g_1 g_2 - 2 g_2^2.$$

Retaining only the terms that are linear in Agijage gives df(&, D&) = [10q1+6q2] Dq, +[6q,+1qi] Dq2.

(c) Following the same procedure.
as in (a) and (b) gives

df(2, 02) = [28, +58283+282] Ag, +[282+58,83 +291] 482 +[58,92+3] 483.

4-4

(a) Expanding the integrand of J(x+sx)-J(x) and retaining only the

linear terms yields  $SJ(x,8x) = \int_{t}^{t} \left[ 3x^{2}(t) - 2x(t) \dot{x}(t) \right] Sx(t).$ 

NOTE: The same result is obtained by using Eq. (4.2-7).

(b) Again expanding the integrand of AJ,

 $SJ(x,8x) = \int_{t}^{t} \left[2x_{1}(t) + x_{2}(t)\right] Sx_{1}(t) + \left[x_{1}(t) + 2x_{2}(t)\right] Sx_{2}(t)$ + [2x2(t)] 5x,(t) + [2x,(t)] 5x2(t)} dt.

 $\Delta J(x,8x) = \int_{1}^{t_{f}} e^{x(t)+8x(t)} - e^{x(t)} dt$ 

 $=\int_{t}^{t_{c}} [e^{sx(t)}e^{x(t)} - e^{x(t)}] dt = \int_{t}^{t_{c}} [1+sx(t)+(sx(t))^{2} + iii] e^{x(t)}$ 

 $\therefore SJ(x,sx) = \int_{a}^{t_f} e^{x(t)} Sx(t) dt.$ 

This result is also obtained by using a Taylor

$$\frac{4-5}{J(x^*+e^*n)} = \int_{t_0}^{t_f} \frac{\partial f(x^*(t)+e^*n(t),\dot{x}^*n(t)+e^*n(t),t)}{\partial t}.$$

$$\frac{dJ(x^*+e^*n)}{de} = \int_{t_0}^{t_f} \frac{\partial f(x^*(t)+e^*n(t),\dot{x}^*n(t)+e^*n(t),t)}{\partial x} \frac{\partial f(x^*(t)+e^*n(t),\dot{x}^*n(t)+e^*n(t),t)}{\partial x} \frac{\partial f(x^*(t)+e^*n(t),\dot{x}^*n(t),t)}{\partial x} \frac{\partial f(x^*(t)+e^*n(t),\dot{x}^*n(t),t)}{\partial x} \frac{\partial f(x^*(t),\dot{x}^*n(t),t)}{\partial x} \frac{\partial f(x^*(t),\dot{x}^*n($$

Integrating by parts, using the requirement that  $n(t_0) = n(t_0) = 0$ , and invoking the fundamental lemma (see problem 4-2), gives the Euler equation.

$$\frac{4-k}{J_d} \approx \Delta t \sum_{k=0}^{N-1} g(x(k), \frac{x(k+1)-x(k)}{\Delta t}, k) .$$

$$\frac{\partial J_d}{\partial x(k)} = \Delta t \left[ \frac{\partial g}{\partial x} \left( x^*(k), \frac{x^*(k+1)-x^*(k)}{\Delta t}, k \right) \right]$$

$$-\frac{1}{\Delta t} \frac{\partial g}{\partial x} \left( x^{*}(k), \frac{x^{*}(k+1) - x^{*}(k)}{\Delta t}, k \right)$$

$$+ \frac{1}{\Delta t} \frac{\partial g}{\partial x} (x^{*}(k-1), x^{*}(k) - x^{*}(k-1), k-1) = 0$$

$$k = 1, 2, ..., N-1.$$

The last two terms are a finite difference approximation to the derivative with respect to time of 03/0%; therefore, taking the limit as At -> 0 gives the Euler equation  $\frac{\partial g}{\partial x} \left( x^*(t), \dot{x}^*(t), t \right) - \frac{d}{dt} \left[ \frac{\partial g}{\partial \dot{x}} \left( x^*(t), \dot{x}^*(t), t \right) \right] = 0.$ 

(a) df = [t2+3++] At=[++] [t+2] At== 0.  $t_d = -1$ ,  $t_z = -2$ 34 = 2++3 34(+1)=+1 => ti is a relative (and absolute) min  $\frac{\partial^2 f}{\partial t^2}(t_2) = -1 \implies t_2$  is a relative (and

(b) 
$$\frac{\partial f}{\partial t} \stackrel{\text{set}}{=} 0 = e^{-zt} - 2te^{-zt}$$

$$\Rightarrow 1-2t = 0 \text{ or } t = \frac{1}{2}$$

$$\frac{\partial^2 f}{\partial t^2} = -2e^{-2t} - 2e^{-2t} + 4te^{-2t}$$

$$= (-4 + 4t)e^{-2t}$$

oti (1/2) is negative, therefore,

Minima.

(c) 
$$df = \begin{bmatrix} 2g_1 + 9 + g_2 \end{bmatrix} \Delta g_1 + \begin{bmatrix} 4g_2 - 1 + g_1 \end{bmatrix} \Delta g_2$$
 $\stackrel{\text{set}}{=} 0$ .

Since  $\Delta g_1 \neq \Delta g_2$  are independent

$$\frac{\partial^2 f}{\partial g^2} = \begin{bmatrix} 2 & 1 \\ 1 & 4 \end{bmatrix}$$
 a positive -- definite matrix, so  $\frac{\partial^2 f}{\partial g^2} = \frac{1}{4}$   $\frac{\partial^2 f}{\partial g$ 

9 \* , 4 \* is a minimum.

@The Euler equation is 2x\*(1)-2x\*(1)=0. The form of the solution -- obtained by classical methods, or Laplace transforms -- is  $\chi^*(t) = c_1 e^{-t} + c_2 e^{t}$ .

Now,  $x^*(0) = 0 \Rightarrow c_1 + c$ , or and  $x^*(1) = 1 \Rightarrow$ ciel+czel+o. Solving these two equations gives  $\frac{1}{c^{-1}-e^{-t}}\left[e^{-t}-e^{t}\right]$ .

(b) The Euler equation is of [2x\*(t)+2x\*(t)]=0, 2x\*(t) + 2x\*(t) - It [2x\*(t)+2x\*(t)]=0,

4-8 (cont.)  
or 
$$x^*(t) - x^*(t) = 0 \Rightarrow x^*(t) = c_1 e^t + c_2 e^{-t}$$
.  
 $x^*(0) = 1 \Rightarrow c_2 = 1 - c_1$ ;  $x^*(2) = -3 = c_1 e^2 + c_2 e^{-2}$ .  
Solving for c, and  $c_2$  gives
$$c_1 = \frac{-3 - e^{-2}}{e^2 - e^{-2}}$$

$$c_2 = \frac{e^2 + 3}{e^2 - e^{-2}}$$
.

(c) The Euler equations are  $x_i^*(t) - x_2^*(t) = 0$ ,  $-x_i^*(t) + x_2^*(t) = 0$ . Differentiating the first equation twice, and adding to the second eq. gives  $\frac{d^4x_i^*(t)}{dt^4} - x_i^*(t) = 0.$ 

This differential equation has the characteristic equation 54-1=0, which has roots  $s=\pm 1,\pm 11$ . The solution has the form

 $x_1^*(t) = c_1 e^{-t} + c_2 e^t + c_3 \cos t + c_4 \sin t$ 

Differentiating this twice and substituting into the first Euler equation yields  $\chi_2^*(t) = c_1 e^{-t} + c_2 e^t - c_3 \cos t - c_4 \sin t$ .

From the specified boundary conditions  $\chi_1^*(0)=0 \Rightarrow c_1+c_2+c_3=0$ ,  $\chi_2^*(0)=0 \Rightarrow c_1+c_2-c_3=0$ .

1.  $c_3=0$ ,  $c_1+c_2=0$ .

 $\chi_1^*(\pi/2) = 1 \Rightarrow c_1 e^{-\pi/2} + c_2 e^{\pi/2} + c_4 = 1$   $\chi_2^*(\pi/2) = c_1 e^{-\pi/2} + c_2 e^{\pi/2} - c_4 = 1$ 

4-8 (cont.) which imply that cq = 0. Solving for c, and  $C_2$  gives  $C_1 = \frac{1}{2 \sinh(\pi/2)}$ and cz = Isinh (T/2); therefore  $\chi_{2}^{*}(t) = \frac{\sinh(t)}{\sinh(\pi/2)} \quad \chi_{2}^{*}(t) = \frac{\sinh(t)}{\sinh(\pi/2)}$ 

4-9

The Euler equation reduces to x\*(t) -4 x\*(t)-4=0.

The form of the solution is  $\chi^*(t) = c_1 e^{2t} + c_2 e^{-2t} + c_3$ .

C3 can be found by substituting this solution into the original differential equation with the result that &= -1. Using the given boundary conditions, we find that  $c_2 = \frac{5-26^2}{6^{-2}-6^2}$  and  $c_1 = 2-c_2$ .

4-10 (a) The Euler eq. is the same as in Prob. 4-8(2), so  $x*(t)=c,e^{-t}+c_2e^t$ . At the 1, the natural b.c. is

 $\frac{\partial g}{\partial \dot{x}}(x^*(1),\dot{x}^*(1)) = 2\dot{x}^*(1) = 0.$ 

 $\therefore \dot{x}^{*(1)} = 0 \implies -c_{1} e^{-1} + c_{2} e^{1} = 0$  $x^*(0)=1 \implies c_1+c_2=1$ 

and the solution is 
$$\frac{1}{e^{-1}+e^{1}} \left[ e^{(1-t)} + e^{-(1-t)} \right] = \chi^{*}(t).$$

(b) The Euler eq. reduces to  $\dot{x}^*(t) = 1$ , which when integrated twice gives x\*(t) = \frac{1}{2}t^2 + c\_1t + c\_2.

The natural boundary condition is

$$\frac{\partial g}{\partial \dot{x}}(x^{*(1)}, \dot{x}^{*(1)}) = \dot{x}^{*(1)} + x^{*(1)} + 1 = 0$$
, so

1+c,+1/2+c,+c2+1=0 ; also x\*(0)=====c2.

Solving for cland cz yields  $\chi^*(t) = \pm t^2 - \frac{3}{2}t + \frac{1}{2}$ .

(c) The Euler egs. and their solutions are the same as in Prob. 4-8(c); therefore,

 $x^*(t) = c_1 e^{-t} + c_2 e^{t} + c_3 \cos t + c_4 \sin t$  $\chi_2^*(t) = c_1 e^{-t} + c_2 e^t - c_3 \cos t - c_4 \sin t$ .

Three of the four b.c. from 4-8(c) also hold so

$$C_1+C_2+C_3=0$$
  $\Rightarrow$   $C_3=0$ ,  $C_1+C_2=0$ 

 $c_1 e^{-\pi/2} + c_2 e^{\pi/2} - c_4 = 1$ .

The fourth relationship is

$$\frac{\partial f}{\partial \hat{x}_{1}} \left( x^{*}(T/2), \hat{x}^{*}(T/2) \right) = 2 \hat{x}_{1}^{*}(T/2) = 0, 50$$

4-10 (cont.)  

$$-c_1 e^{-TT/2} + c_2 e^{TT/2} = 0$$
.  
Solving for  $c_{1}, c_{2}, and c_{4}$  leads to  $x_1^*(t) = -\sin(t)$   $x_2^*(t) = \sin(t)$ .

A-11  
Introducing variations 
$$Sx, S\dot{x}, S\dot{x}, ..., S\dot{x}$$
  
gives
$$SJ = \int \left[ \frac{\partial t}{\partial x} Sx + \frac{\partial t}{\partial \dot{x}} S\dot{x} + ... + \frac{\partial t}{\partial \dot{x}} S\dot{x} \right] dt$$

(omitting arguments).

Integrating by parts the terms containing derivatives of 
$$8x$$
 gives  $8J = \frac{\partial g}{\partial \dot{x}} 8x \Big|_{to}^{tf} + \frac{\partial g}{\partial \dot{x}} 8x \Big|_{to}^{tf} + \cdots + \frac{\partial g}{\partial \dot{x}} 8x \Big|_{to}^{tf}$ 

$$+ \int_{t_0}^{t_0} \frac{\partial g}{\partial x} s \times - \left( \frac{d}{dt} \left[ \frac{\partial g}{\partial x} \right] \right) s \times - \cdots - \left( \frac{d}{dt} \left[ \frac{\partial g}{\partial x} \right] \right)$$

$$\cdot s \times \left( \frac{(r-1)}{2} \right) dt.$$

The specified boundary conditions imply that sx, sx, ..., sx are zero at t=to and at t=tf, so the terms outside the integral are all zero. Continuing to integrate by parts, using the specified boundary conditions, 4-11 (cont.)
applying the fundamental theorem, and calling on the fundamental lemma yields the Euler eq. of rth order.

$$\sum_{k=0}^{r} (-1)^k \frac{d^k}{dt^k} \left[ \frac{\partial \theta}{\partial x^k} (x^*(t), ..., \frac{d^r x^*}{dt^r}(t), t) \right] = 0.$$

4-12

(a) The Euler eq. is 
$$\frac{d^4 x^*}{dt^4}(t) = 0 ; therefore$$

$$\chi*(t) = c_1 t^3 + c_2 t^2 + c_3 t^3 + c_4$$
  
 $\chi*(0) = 0 \implies c_4 = 0$ 

$$\dot{x}^*(0) = 1 \implies c_3 = 1$$

$$\chi*(1)=2 \implies c_1+c_2+1=2$$

$$x^*(1) = 4 \implies 3c_1 + 2c_2 + 1 = 4.$$

After solving these, we have  $x^*(t) = t^3 + t$ .

(b) The Euler eg.

$$\frac{d^4 x^*}{dt^4}(t) - 3x^*(t) + x^*(t) = 0$$

has the characteristic equation

and characteristic roots 5=+1+11-1-1.

The solution has the form  $x*(t)=c_1e^t+c_2te^t+c_3e^{-t}+c_4te^{-t}$ .

Since 
$$x^*(\omega) = \dot{x}^*(\omega) = 0$$
,  $c_1 = 0$ ,  $c_2 = 0$ .

 $x^*(0) = 1 \implies c_3 = 1$ 
 $\dot{x}^*(0) = 2 \implies -c_3 + c_4 = 2$ .

Solving yields

 $x^*(t) = e^{-t} + 3te^{-t}$ .

4-13

The solution of the Euler eq.

 $\ddot{x}^*(t) = 0$ 

is  $x^*(t) = c_1t + c_2$ .

 $x^*(0) = 2 \implies c_2 = 2$ ,

 $x^*(t) = c_1t_1 + 2 = -4t_1 + 5$ 

and, from the transversality condition

Eq.  $(4.2-72)$ 
 $\frac{\dot{x}^*(t)}{[1+\dot{x}^*]^{1/2}} \left\{ -4-\dot{x}^*(t) \right\} + \left[ 1+\dot{x}^*]^{1/2} = 0$ 

We obtain  $\dot{x}^*(t) = c_1 = 1/4$ 

4-14
After simplification, the Euler eq.
becomes  $x^*(t) \dot{x}^*(t) + \dot{x}^{*2}(t) = -1.$ 

:. x\*(t)= 1 t+2.

The left side of this nonlinear d.c. is the exact derivative of

65

$$\frac{d}{dt} \left[ \chi * (t) \dot{\chi} * (t) \right] = -1 \implies \chi * (t) \dot{\chi} * (t) = -t + c_1.$$

But

$$\frac{1}{2} x^{*2}(t) = -\frac{1}{2} t^2 + c_1 t + c_2.$$

The transversality condition leads to

$$1+\dot{\chi}^*(t_f)=0.$$

Solving for c, and to gives  $c_1=5$  $t_7=5\pm\sqrt{15}/2$ ; and

$$\chi^{*2}(t) = -t^2 + /0t$$
.

4-15

The Euler eq. reduces to  $\dot{x}^*(t) = 0$ , hence,  $x^*(t) = c_1 t + c_2$ , and  $x^*(0) = 5$  implies that  $c_2 = 5$ .

In finding  $c_1$ , the problem is that in Eq. (4.2-65)  $5x_f$  and  $5t_f$  are related;

let us now show two ways of finding the appropriate relationship. Let  $m(x(t), t) \triangleq x^2(t) + (t-5)^2 - 4 = 0$ .

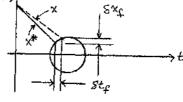

(i) m(x\*(tf), tf) must equal zero, as must m(x\*(tf)+8xf, tf+8tf) (to first-order in 8xf, and 8tf). Expanding m(x\*(tf)+8xf, tf+8tf) gives

 $x^{*2}(t_f) + 2x^{*}(t_f) \delta x_f + [\delta x_f]^2 + t_f^2 + 2t_f \delta t_f$ -10  $t_f + [\delta t_f]^2 - 10 \delta t_f + 21$ .

using the fact that m(x\*(tf),tf)=0 and dropping second-order terms we have

 $2x^*(t_f) \delta x_f + 2(t_f-5) \delta t_f = 0$ , which is the required relationship.

(ii) Let us now consider a geometric approach; the curve m(x(t),t)=0, a possible extremal curve  $x^*$ , and a neighboring curve x are shown below.

4-15 (cont.)

From the diagram it is seen that, to first order, 8xp = d8tp, where a is the slope of the tangent to the circle at the point x\*(tf), tf.

Then, to find this slope we note

 $dm = 0 = \frac{\partial m}{\partial x} \delta x_f + \frac{\partial m}{\partial t} \delta t_f$ 

 $2 \times (t_f) \delta x_f + 2(t_f - \epsilon) \delta t_f = 0$ .

Either approach leads to the result.

$$8x_f = \frac{-(t_f - t_f)}{x^*(t_f)} St_f.$$

We next substitute this for Sxo in the equation (4.3-18)

3x (\*, tr) 3xx +[3(\*, tr) - 3x (\*, tr) x\*(tr) 3tr = 0.

Performing algebraic simplification leads to

$$(5-t_{\varphi})c_1+c_1t_{\varphi}+5=0 \implies c_1=-1$$

 $x^*(t) = -t + 5$ .

From Prob. 4-14, the form of the solution to the Fuler eq. is

$$\frac{1}{2} \chi^{*Z}(t) = -\frac{t^{z}}{2} + c_{1}t + c_{2}$$

Since x\*(0) = 0, we have Cz = 0. Using the approach given in Prob. 4-15, we find that at the final time the relationship

 $2(t_f-9)$  Stf +  $2x^*(t_f)$  Sxf = 0 must be satisfied. Solving this equation for  $8x_f$ , substituting into the boundary-condition equation

 $0 = \frac{\partial g}{\partial \dot{x}} (*, t_f) \quad s \times_f + \left[ g(*, t_f) - \dot{x}^*(t_f) \frac{\partial g}{\partial \dot{x}} (*, t_f) \right] \times_f$ and simplifying gives

$$-\dot{\chi}^{*}(t_{f})(t_{f}-q)+\chi^{*}(t_{f})=0. \tag{I}$$

To obtain x\*(tx), we differentiate

$$\frac{1}{2} \chi^{*2}(t) = -\frac{t^2}{2} + c, t \tag{II}$$

with respect to time to obtain

$$x^*(t) \dot{x}^*(t) = -t + c_1.$$
 (211)

Solving (III) for  $x^*(t)$ , letting  $t=t_f$ , and substituting in (I) leads to

$$(t_f-c_i)(t_f-q)+x^{*2}(t_f)=0$$
. (IF)

using (II) in (IV) and in the constraint equation, we obtain

$$4-16$$
 (cont.)  
 $c_1t_f-9t_f+9c_1=0$   
and  
 $18t_f-2c_1t_f-7z=0$ .

Solving these simultaneously yields 
$$c_1 = 4$$
,  $t_f = 7.2$ , so  $\chi^{*2}(t) = -t^2 + 8t$ .

(a) From 
$$4-8(c)$$
  
 $x_1^*(t) = c_1 e^{-t} + c_2 e^{t} + c_3 \cos t + c_4 \sin t$  (I)  
 $x_2^*(t) = c_1 e^{-t} + c_2 e^{t} - c_3 \cos t - c_4 \sin t$  (II)

From the specified initial conditions:

$$0 = c_1 + c_2 + c_3$$

$$0 = c_1 + c_2 - c_3$$
(III)

$$(IV)$$

From the specified Q(t):

$$5t_1 + 3 = c_1e^{-t_1} + c_2e^{t_1} + c_3 \cos t_1 + c_4 \sin t_1 (\mathbf{x})$$

$$\frac{1}{2}t_{f}^{2} = c_{1}e^{-t_{f}} + c_{2}e^{t_{f}} - c_{3}\cos t_{f} - c_{4}\sin t_{f}.$$

From Entry 5. of Table 4-1:

$$\left\{3 + \left[\frac{\partial g}{\partial \dot{x}}\right]^{\top} \left[\frac{\partial g}{\partial t} - \dot{x}\right]\right\}_{\dot{X}^{*}(t_{\varphi})} \dot{X}^{*}(t_{\varphi}) t_{\varphi} = 0.$$

substituting  $\begin{bmatrix} \frac{\partial g}{\partial \dot{x}} \end{bmatrix}^T = \begin{bmatrix} 2\dot{x}_1 & 2\dot{x}_2 \end{bmatrix}$  and

$$\frac{d\theta}{dt} = \begin{bmatrix} 5 \\ t \end{bmatrix}$$
, and simplifying, yields

4-17 (cont.)

x\* and x\* are found by differentiating (II) with respect to time.

(II) and (III) with respect to time.

Equations (III) through (VII) must be solved for the five unknowns c1,02,03,04, tf.

(b) Equations (III) and (IV) from part (a) must again be Eatisfied.

From the specified terminal constraint:

$$x^{*}(t_{f}) + 3x^{*}(t_{f}) + 5t_{f} = 15.$$
 (XIII)

Using the approach discussed in Prob. 4-15, we find that

5x1+ 35x2+ +5 stf = 0

 $\Rightarrow$   $\mathbf{S}_{1} = -3 \mathbf{S}_{2} - \mathbf{S}_{5} t_{\mathbf{f}}$ .

Substituting this expression into

$$\left\{ \begin{bmatrix} \frac{\partial \mathfrak{J}}{\partial \dot{x}} \end{bmatrix}^{\mathsf{T}} \mathbf{5} \times \mathbf{f} + \left[ \mathbf{3} - \left( \frac{\partial \tilde{x}}{\partial \dot{x}} \right)^{\mathsf{T}} \dot{x} \right] \mathbf{5} \mathbf{f}_{\mathsf{f}} \right\} = 0$$

and collecting terms gives an equation of the form

0=f,  $(x^*(t_f), \dot{x}^*(t_f), t_f)$   $8x_{z_f} + f_z(x^*(t_f), \dot{x}^*(t_f), t_f) St_f$ . Since  $8x_{z_f}$  and  $St_f$  are independently arbitrary,

$$f_1(x_*(f^t), \dot{x}_*(f^t), f^t) = 0 \qquad (Ix.)$$

$$f_2\left(\chi^*(t_f), \dot{\chi}^*(t_f), t_f\right) = 0. \tag{X}$$

4-17 (cont.)

Equations  $(\Pi)$ ,  $(V\Pi)$ ,  $(V\Pi)$ , and (X)

must then be solved for cucz, cz, cz, ca, and tf.

NOTE: The decision to solve the

eg. 8x, +38x2++55t = 0

for \$x\_1 is arbitrary, we could have solved for \$x\_2, or \$t\_fand proceeded in the same way.

4-18

The solution of the Euler eq. is  $X^*(t) = c_1 t + c_2$ ,  $t \in [-2, t,]$ 

= c3t + c4 ) te[t,, 1].

The boundary conditions are

 $x^*(-2) = 0 = -2c_1 + c_2$  $x^*(1) = 0 = c_3 + c_4$ 

c, t, +c2 = t,2+2

 $c_3 t_1 + c_4 = t_1^2 + 2$ 

and, from the Weierstrass-Erdmann corner conditions,

$$\frac{2t_1c_1+1}{\left[1+c_1^{\ 2}\right]^{1/2}} = \frac{2t_1c_3+1}{\left[1+c_3^{\ 2}\right]^{1/2}}.$$

solving these five egs, simultaneously gives

4-18 (cont.)

$$x^{*}(t) = \begin{cases} 1.039t + 2.077, t \in [-2, -.0696] \\ -1.874t + 1.874, t \in [-.0696, ]. \end{cases}$$

4-19

From the Weierstrass-Erdmann corner condition (4.4-5a)

$$\frac{\partial \vec{x}}{\partial \theta} \left( x^*(t_i), \vec{x}^*(t_i^-), t_i \right) = \frac{\partial \vec{x}}{\partial \theta} \left( x^*(t_i), \vec{x}^*(t_i^+), t_i \right)$$

 $2a\dot{x}^*(t_i) + bx^*(t_i) = 2a\dot{x}^*(t_i) + bx^*(t_i)$ 

Since a =0, this implies that

$$\dot{x}^*(t^-) = \dot{x}^*(t^+)$$

hence there can be no corners.

4-20

Since & depends only on x(t), the solution of the Euler eg. is ( See Appendix 3, case 1)

$$x^*(t) = c_1 t + c_2$$
,  $t \in [0, t]$ 

$$\chi^*(0) = 0 \implies c_z = 0$$

$$\chi^{*}(4) = 2 \implies 4c_3 + c_4 = 2.$$

writing out the Weierstrass-Erdmann corner conditions, we see that  $\dot{x}^*(t_1) = \pm 1$  and  $\dot{x}^*(t_1) = \pm 1$ 

satisfy these conditions.

4-20 (cont.)

(i) suppose  $\dot{x}^*(t_1)=1$ ,  $\dot{x}^*(t_1)=1$ , then  $c_1=1$ ,  $c_3=-1$ ,  $4c_3+c_4=2$ ,

and  $c_1t_1=c_3t_1+c_4$   $\dot{x}^*(t_1)=\frac{1}{2}$ ,  $\dot{x}^*(t_1)=\frac{1}{2}$ ,  $\dot{x}^*(t_1)=\frac{1}{2}$ .  $\dot{x}^*(t_1)=\frac{1}{2}$   $\dot{x}^*(t_1)=\frac{1}{2}$   $\dot{x}^*(t_1)=\frac{1}{2}$   $\dot{x}^*(t_1)=\frac{1}{2}$ (ii) Suppose  $\dot{x}^*(t_1)=-1$ ,  $\dot{x}^*(t_1)=\frac{1}{2}$ , then  $c_1=-1$ ,  $c_3=+1$ ,  $4c_3+c_4=2$ , and  $c_1t_1=c_3t_1+c_4$   $\dot{x}^*(t_1)=\frac{1}{2}$   $\dot{x}^*(t_1)=\frac{1}{2}$   $\dot{x}^*(t_1)=\frac{1}{2}$ 

 $\therefore x^{*(t)} = \begin{cases} -t, & t \in [0,1] \\ t-2, & t \in [1,4]. \end{cases}$ 

Both of these curves yield J=0, which is clearly the absolute minimum of J.

4-21  $f_a = y_1^2 + y_2^2 + py_2 - py_1^2 + 4.5p$ setting  $df_a = 0$  gives

setting  $df_{1} = 0$  gives  $2y^{*} - 2y^{*} p^{*} = 0$  (I)  $2y^{*} + p^{*} = 0$  (II)

 $y_2^* - y_1^{*2} + 4.5 = 0,$  (DI)

4-21 (cont.)

74

where we have used the argument in the text to equate the coefficients of Ayı, Ayz, and Af to zero.

Fq. (I) implies that  $y^*[1-p^*]=0$ , and either  $y^*=0$ , or  $p^*=1$  (or both).

(i) If  $y_1^*=0$ , (III) gives  $y_2^*=-4.5$ , and from (II)  $p_1^*=9$  (not necessary to find  $p_1^*$ ).

(ii) If  $p^* = +1$ , (II) gives  $y_2^* = -\frac{1}{2}$ , and from (III)  $y_1^{*2} = 4$ ,  $y_1^* = \pm 2$ .

For (i)  $f = [4.5]^2 = 20.25$ , and for (ii)

 $f = 4 + \frac{1}{4} = 4.25$ .

Therefore, the minimizing points are  $y^* = \pm 2$ ,  $y^* = -1/2$ .

4-22

 $f_{\alpha} = y_1^2 + y_2^2 + y_3^2 + p_1[y_1 + y_2 + y_3 - 5] + p_2[y_1^2 + y_2^2 + y_3 - 9].$ 

From dfa = 0, we obtain the necessary conditions

$$2y^* [1+p^*] + p^* = 0$$
 (1)

$$2y_{2}^{*} [1+p_{2}^{*}] + p_{1}^{*} = 0$$
 (m.)  
 $2y_{3}^{*} + p_{1}^{*} + p_{2}^{*} = 0$  (m.)

$$4-22 (cont.)$$
 75  
 $y^* + y^* + y^* - 5 = 0$  (IV)

 $y^{*2} + y_{2}^{*} + y_{3}^{*} - 5 = 0$   $y^{*2} + y_{2}^{*2} + y_{3}^{*} - 9 = 0.$ (52)

(I) and (II) imply y\*=y\*, or p\*=-1.

(i) suppose  $y_1^* = y_2^*$ . Substituting in (IV) and (IV) gives  $2y_1^* + y_2^* = +5$ ,  $2y_1^* + y_2^* = 9$ .

Eliminating  $y_3^*$  yields  $y_1^{*2} - y_1^* - 2 = 0 \implies y_1^{*} = +2, \text{ or } -1$ 

therefore,  $4\frac{2}{2} = +2$ , or -1, and  $4\frac{2}{3} = 5 - 2\{\frac{2}{-1}\} = +1$ , or +7, and  $4\frac{2}{3} = \begin{bmatrix} 2 \\ 2 \\ 1 \end{bmatrix}$ , or  $4\frac{2}{3} = \begin{bmatrix} -1 \\ -1 \\ 1 \end{bmatrix}$ .

(ii) suppose  $p_2^* = -1$   $\Rightarrow p_1^* = 0$  $2y_3^* + p_1^* = +1$  or  $y_3^* = 1/2$ 

 $y_1^* + y_2^* = 4.5$ 

y\*2+y\*2 = 8.5.

Fliminating  $y^*$  gives  $(4.5-y^*)^2 + y^{*2} = 8.5$  $20.25 - 9y^* + 2y^{*2} = 8.5$ . It turns out that there are no real rects to this equation, so the only possible solutions are given in (1).

By inspection of the alternatives,

y\* = [2 2 ] is the closect

point to the origin that lies

on the specified constraints.

## 4-23

Integrating the terms in Eq. (4.5-39) that contain  $S\dot{w}(t)$ , we obtain (considering an extremal curve)

$$\left\{ \begin{bmatrix} \frac{\partial g}{\partial \hat{w}} (*,t) + 2^{*}(t) & \frac{\partial f}{\partial \hat{w}} (*,t) \end{bmatrix} \delta w(t) \right\}_{t_0}^{t_f}$$

+ the integral term in Eq. (4.5-40). SW(to) = Q, so the terms at to unish Allowing to be free introduces

the additional terms

$$\left\{g(*,t_f) + p^{*T}(t_f) \left[f(*,t_f)\right]\right\} St_f.$$

Finally, using the relationship  $Sw(t_f) \doteq Sw_f - iv^*(t_f) St_f$ ,

77

4-23 (cont.)

and collecting terms yields

 $\left\{\frac{9\ddot{m}}{93_{\perp}}(*)^{+t} + 5_{*,\perp}(t^{t})\frac{9\ddot{m}}{9t}(*)^{+t}\right\}$  \$\tilde{n}^{t}\$

 $+ \left[ 3(*)^{t_{f}} + 2^{*T}(t_{f}) \frac{5t}{5w} (*)^{t_{f}} \right] \frac{3t}{5w} (*)^{t_{f}}$   $+ 2^{*T}(t_{f}) \frac{3t}{5w} (*)^{t_{f}}$   $+ 2^{*T}(t_{f}) \frac{3t}{5w} (*)^{t_{f}}$ 

+ the integral in (4.5-40) = SJa. evaluated on an extremal

4-24

 $(a) g_{\alpha} = w_1^2(t) + w_1(t) w_2(t) + w_2^2(t) + w_3^2(t) + p_1(t) \left[ w_2(t) - \dot{w}_1(t) \right] + p_2(t) \left[ -w_1(t) + (1 - w_1^2(t)) w_2(t) + w_3(t) - \dot{w}_2(t) \right]$ 

 $2 w_1^*(t) + w_2^*(t) + p_2^*(t) [-1 - 2 w_1^*(t) w_2^*(t)] = -p_1^*(t)$  $w_1^*(t) + 2 w_2^*(t) + p_1^*(t) + p_2^*(t) [1 - w_1^*(t)] = -p_2^*(t)$ 

 $2w_3^*(t) + p_2^*(t) = 0$ 

and the original differential conditions are necessary conditions for optimality.

(b)  $g_a = \lambda + w_3^2(t) + P(t) [w_2(t) - \hat{w}_1(t)] + P_2(t) [w_3(t) - \hat{w}_2(t)]$ 

5\*(1) - 0

A\*(t)=0

2 w3\*(t) + p2\*(t) = 0

and the original die, are necessary for optimality.

(c) 
$$g_1 = \lambda + w_3^2(t) + \rho_1(t) \left[ w_2(t) - \hat{w}_1(t) \right] + \rho_2(t) \left[ -w_2(t) | w_2(t) | + w_3(t) - \hat{w}_2(t) \right]$$

 $\dot{\rho}_{\rm I}^*(t) = 0$ 

$$p_{z}^{*}(t) = -p_{z}^{*}(t) + 2p_{z}^{*}(t) | w_{z}^{*}(t) |$$

 $0 = -2 \omega_3^*(t) - P_2^*(t)$ 

and the original d.e. equation constraints must be satisfied by an optimal trajectory.

4-25  $g_a = \dot{\chi}^2(t) + t^2 + p(t) \left[ \chi^2(t) - \dot{z}(t) \right]$ 

$$\dot{p}^*(t) = 0 \Rightarrow p^*(t) = c_1$$

are necessary for optimality; hence,

$$\sqrt{x}*(t) - c_1 x*(t) = 0$$
.

The solution of this d.e. is one of the two forms

$$x*(t) = c_3 \cos(c_2 t) + c_4 \sin(c_2 t) c_2 = |c_1|$$

cr, x\*(1) = c'2 E-C2t + c'1 E C2t, c2-Ve1 where the first solution covers.

ponds to ciko, and the second

solution conceptants to cisc.

It can be shown that if ciso, the Loundary conditions xx(1). xx(1):0 require that conditions xx(1):0. clearly, this solution cannot salisfy

5 xx2(t) d1 = 2,

so of must be less than germ.

Thus, x\*(t) -. czces(czt)+cqsin(c,t)

x\*(1)=0 -> C3=0 x\*(1)=0-> casin(c)=0, which reguines that

Cz = + hT , N = 4,2, ...

and

( c4 sin2 (mit) di = 2

1. CA = 5/h (2011 0) = 5/2 . . .

C4 = 4 C4 - + 2 x\*(t) = = = = = in (nit), n: 1,2, ...

$$J = \frac{1}{2} \int_{0}^{\infty} [\dot{w}_{1}^{2}(t) + \dot{w}_{2}^{2}(t) + \dot{w}_{3}^{2}(t)] dt.$$

$$g_{\alpha} = \frac{1}{2} \left[ \dot{w}_{1}^{z}(t) + \dot{w}_{2}^{z}(t) + \dot{w}_{3}^{z}(t) \right] + \rho(t) \quad f(w_{1}(t), w_{2}(t), w_{3}(t))$$

$$\overline{w_i}^*(t) = p^*(t) \frac{\partial f}{\partial w_i}(*,t)$$

$$\dot{w_z}^*(t) = f^*(t) \frac{\partial f}{\partial w_z}(*,t)$$

$$\dot{w_3}^*(t) = p^*(t) \frac{\partial f}{\partial w_3}(*,t).$$

Therefore,
$$p^{*}(t) = \frac{\ddot{w}_{1}^{*}(t)}{\frac{\partial f}{\partial w_{1}}(*,t)} = \frac{\ddot{w}_{2}^{*}(t)}{\frac{\partial f}{\partial w_{2}}(*,t)} = \frac{\ddot{w}_{3}^{*}(t)}{\frac{\partial f}{\partial w_{3}}(*,t)}.$$

5-1
(a) Let the x and y coordinates of the boat be the state variables, then

$$\dot{\chi}(t) = V \cos \beta(t)$$
  
 $\dot{y}(t) = -V \sin \beta(t) + S(\chi(t)).$ 

(b) 
$$\lambda = 1 + p_1(t) \vee \cos \beta(t) - p_2(t) \vee \sin \beta(t) + p_2(t) \leq (x(t))$$

$$\dot{\rho}_{1}^{*}(t) = -\rho_{2}^{*}(t) \frac{\partial s}{\partial x} (x^{*}(t))$$

$$0 = \frac{\partial \mathcal{L}}{\partial \beta}(*_{j}t) = -p_{j}^{*}(t) \vee sin_{\beta}^{*}(t) - p_{j}^{*}(t) \vee cos_{\beta}^{*}(t)$$

and the state differential egs. are necessary conditions for optimal control.

$$(c)' \lor > S(x(t))$$

(4) 
$$\dot{p}_i^*(t) = 0 \Rightarrow \dot{p}_i^*(t) = c_i$$

$$\dot{\rho}_{z}^{*}(t) = 0 \Rightarrow \dot{\rho}_{z}^{*}(t) = c_{z}$$
  
and  $\partial \mathcal{K}/\partial \beta = 0 \Rightarrow -c_{i} \sin \beta^{*}(t) = c_{z} \cos \beta^{*}(t)$ 

therefore,

$$\frac{\sin \beta^*(t)}{\cos \beta^*(t)} = a \ constant \Rightarrow \beta^*(t) = a \ const.$$

82

5-2

For  $|p_2*(t)| \le 1$ , the minimizing value of u(t) is as given in part (i). For  $|p_2*(t)| > 1$ , select u(t) to make )t as negative as possible (treating x\*(t), p\*(t) as being fixed), that is, minimize  $\frac{1}{2}u^2(t) + p_2*(t) u(t)$  with respect to admissible values of u(t), Performing this minimization gives  $u*(t) = \begin{pmatrix} -1 & p_2*(t) > 1 \\ -p_2*(t) & -1 \le p_2*(t) \le 1 \\ +1 & p_2*(t) < -1 \end{cases}$ 

5-3
(a)  $\times = \frac{1}{2} u^{2}(t) + \rho_{1}(t) x_{2}(t) - \rho_{2}(t) x_{1}(t) + \rho_{2}(t) [1 - x_{1}^{2}(t)] x_{2}(t) + \rho_{2}(t) ult)$ 

5-3 (cont.)
$$\dot{\rho}_{1}^{*}(t) = -\frac{3x}{3x_{1}}(*_{1}t) = \rho_{2}^{*}(t) + 2\rho_{2}^{*}(t) \propto_{1}^{*}(t) \times_{2}^{*}(t)$$

$$\dot{\rho}_{1}^{*}(t) = -\frac{3x}{3x_{1}}(*_{1}t) = \rho_{2}^{*}(t) + 2\rho_{2}^{*}(t) \propto_{1}^{*}(t) \times_{2}^{*}(t)$$

$$\dot{p}_{2}^{*}(t) = -\frac{\partial \mathcal{X}}{\partial x_{2}}(*)t) = -p^{*}(t) - p_{2}^{*}(t) \left[1 - \chi^{*2}(t)\right].$$

(b)(1)
$$\frac{\partial X}{\partial u}(*,t) = 0$$
 Since u not bounded, and  $X = 0$  and  $X = 0$  since u. This gives  $u^*(t) = -\rho_2^*(t)$ .

$$u^{*}(t) = -p_{2}^{*}(t).$$
(ii) using the same reasoning as in
(b) (ii) of Prob. 5-2 gives
$$\begin{pmatrix} -1 & p_{2}^{*}(t) > 1 \\ -p_{2}^{*}(t) & -2 \le p_{2}^{*}(t) \le 1 \\ +2 & p_{2}^{*}(t) < -2.$$

(c) 
$$t_f$$
 free ,  $m(x(t),t) = 15x_1(t) + 20x_2(t) + 12t - 60$   
See Entry 8. in Table 5-1.

$$-2^*(t_f) = d \begin{bmatrix} 15 \\ 20 \end{bmatrix}$$

$$\mathcal{H}(*)^{t_f} = 12d$$
.

12(t) u(t) + |u(t)|.

Since It is piecewise linear in U(t), we know that the minimizing control occurs on a boundary. Performing the minimization

yields

$$u^{*}(t) = \begin{cases} -1, & |< p_{2}^{*}(t)| \\ 0, & -|< p_{2}^{*}(t)| < 1 \\ +1, & p_{2}^{*}(t)| < -1. \end{cases}$$

If 
$$p_{2}^{*}(t) = +1$$
,  $-1 \le u^{*}(t) \le 0$ , if  $p_{2}^{*}(t) = -1$ ,  $0 \le u^{*}(t) \le 1$ .

(c) 
$$[x^*(t_f) - 4]^2 + [x^*(t_f) - 5]^2 + [t_f - 2]^2 - 9 = 0$$

$$-x^{*}(t_{f}) = 2 d \left[ x^{*}(t_{f}) - 4 \right]$$

$$x^{*}_{2}(t_{f}) - 5$$

5-5 \*\* (& th), y (th), \$ (th) = g(& (th), y (th)) + p (t) & (& (t), y (t)).

From the boundary conditions we have  $\mathcal{K}(\mathcal{X}^*(t_f), \mathcal{U}^*(t_f), \mathcal{Z}^*(t_f)) = 0$ .

The total derivative of It with respect to time is

5-4 (cont.)

P2(t) u(t) + |u(t)|.

Since H is piecewise linear in u(t), we know that the minimizing control occurs on a boundary. Performing the minimization yields

$$u^{*}(t) = \begin{cases} -1, & |< p_{2}^{*}(t)| \\ 0, & -|< p_{2}^{*}(t)| < 1 \\ +1, & p_{2}^{*}(t)| < -1. \end{cases}$$

If 
$$p_2^*(t) = +1$$
,  $-1 \le u^*(t) \le 0$ , if  $p_2^*(t) = -1$ ,  $0 \le u^*(t) \le 1$ .

(c) 
$$[x^*(t_f)-4]^2+[x_2^*(t_f)-5]^2+[t_f-2]^2-9=0$$

$$-x^{*}(t_{f}) = 2 d \left[ x_{1}^{*}(t_{f}) - 4 \right]$$

$$\times_{2}^{*}(t_{f}) - 5$$

5-5  $\mathcal{K}(x), y(t), x(t)) = g(x(t), y(t)) + p(t) g(x(t), y(t)).$ 

From the boundary conditions we have  $\mathcal{K}(x^*(t_f), \mu^*(t_f), x^*(t_f)) = 0$ .

The total derivative of X with respect to time is

5-6 (cont.)

is p\*(T)=0, and the solution of the state-costate die, has

the form 
$$x^*(T) = \varphi_{ij}(T-t) x^*(t) + \varphi_{i2}(T-t) p^*(t) (T)$$

 $P^{*}(T) = 0 = \varphi_{z_1}(T-t) x^{*}(t) + \varphi_{z_2}(T-t) P^{*}(t)$ 

where the \$9's are the components of the state-costate transition matrix

for the linear, homogeneous, const. coef. system 
$$\begin{cases} \dot{\chi}*(t) = \chi*(t) - \rho^*(t) \\ \dot{p}*(t) = -3\chi*(t) - \rho^*(t) \end{cases} \begin{cases} \dot{\chi}*(t) \\ \dot{p}*(t) = -3\chi*(t) - \rho^*(t) \end{cases}$$

Actually, we only need to calculate 921 and 922 because from (II) above

$$p^*(t) = -\varphi_{22}^{-1}(\tau - t) \varphi_{21}(\tau - t) x^*(t)$$

By standard methods we find that

$$\varphi_{21}(t) = \frac{3}{4}(e^{-2t} - e^{2t})$$

$$\varphi_{22}(t) = \frac{1}{4} \left( 3e^{-2t} + e^{2t} \right)$$

therefore, 
$$u^*(t) = \frac{3\left[e^{-2(T-t)} - e^{2(T-t)}\right]}{\left[3e^{-2(T-t)} + e^{2(T-t)}\right]} \times (t)$$

(we drop the \* on x\*(t) because the optimal control law applies for all x(t)).

(b) As  $T \rightarrow \infty$ ,  $u^*(t) \rightarrow -3\chi(t)$ .

5-7

5-6 (cont.)

A problem of the linear regulator type.

(a)  $\mathcal{H} = u^{2}(t) + p(t) u(t) - p(t) a x(t)$  $\dot{p}^{*}(t) = a p^{*}(t)$ 

 $\frac{\partial \mathcal{X}}{\partial u}$  (\*,t) = 0 = 2u\*(t) + p\*(t), or u\*(t) = -\frac{P\*(t)}{2}

 $\begin{bmatrix} \dot{x}^{*}(t) \\ \dot{p}^{*}(t) \end{bmatrix} = \begin{bmatrix} -a & -1/2 \\ 0 & a \end{bmatrix} \begin{bmatrix} x^{*}(t) \\ p^{*}(t) \end{bmatrix}.$ 

The 9 matrix for this system is

$$\mathcal{G}^{(t)} = \begin{bmatrix} e^{-at} & \sqrt{a} \left[ e^{-at} - e^{at} \right] \\ o & e^{at} \end{bmatrix}.$$

Hence, we have

 $\chi^*(\tau) = \varphi_{11}(\tau) \chi^*(0) + \varphi_{12}(\tau) p^*(0). (I)$ 

Letting T=T gives

 $x^*(T) = 0 = \varphi_{i,i}(T) x^*(0) + \varphi_{i,i}(T) p^*(0), or$ 

 $p^{*}(0) = -\varphi_{12}^{-1}(\tau) \varphi_{11}(\tau) \times^{*}(0).$ 

5-7 (cont.)

Letting 
$$T = t$$
 in (I) gives

 $x^*(t) = \varphi_{ii}(t) x^*(0) + \varphi_{i2}(t) p^*(0)$ , or

 $x^*(t) = \left[\varphi_{ii}(t) - \varphi_{i2}(t) \varphi_{i2}(T) \varphi_{i}(T)\right] x^*(0)$ .

Substituting in this expression gives

 $x^*(t) = \left[e^{-ait} - \left(e^{-ait} - e^{ai}\right) e^{-ait}\right] x^*(0)$ 

which applies for all  $x^*(0)$ , so we write  $x(0)$ .

(b)  $p^*(t) = \varphi_{i2}(t) \varphi_{i}(T) \varphi_{i}(T) x^*(0)$ 
 $= -\varphi_{i2}(t) \varphi_{i2}(T) \varphi_{i}(T) x^*(0)$ 

and

$$u^*(t) = \frac{1}{2} \varphi_{22}(t) \varphi_{12}^{-1}(7) \varphi_{1}(\tau) \chi(0)$$

$$= \frac{1}{2} e^{-\alpha t} \left( \frac{4\alpha}{e^{-\alpha T} \cdot e^{-\alpha T}} \right) e^{-\alpha T} \chi(0)$$

$$u^*(t) = \frac{2\alpha e^{-\alpha (T - t)}}{e^{-\alpha T} \cdot e^{-\alpha T}} \chi(0).$$

(c) From the solution of i'll statecostate equations,  $x*(\tau) = 0 = q_{11}(\tau - t) x*(t) + q_{12}(t - t) p*(t),$  $p^*(t) = -q_{12}^{-1}(\tau - t) \varphi_{11}(\tau - t) x^*(t) ;$ nence  $u^*(t) = \frac{2a \in -a(T-t)}{e^{-a(T-t)} - e^{a(T-t)}} \times (t.)$ hence

(we drop the \* from x\*(1) becomes the expression for u\*(t) is valid for all state values).

(d) As  $t \rightarrow T_{j} F(t,T_{j}a) \rightarrow \infty$   $(1*(t) \rightarrow 2a \times (0)$ 

 $u^*(t) \rightarrow \frac{2a \times (0)}{e^{-aT} - e^{aT}}.$ 

This is reasonable physically since for the specified plant to reach the origin control must be applied as t->T, but since x(T) -0, the Seedback gain matrix must approach Infinity to generate a non-zero control value.

As  $T \to \infty$ ,  $F(t, T, a) \to \frac{2ae^{-a(r-t)}}{-ea(r-t)}$ .

Which is small except that when  $t \to T$  we have the same result as before, that is

F→∞, u\*(7+) ≠0.

ナモ= 士 x (t) 定性) な(t) + = 以 (t) R(t) 及(t) + 2+(t) [A(t) &(t) + B(t) &(t)]  $\frac{\partial \mathcal{L}}{\partial u}(*,t) = 0 = R(t) u^*(t) + B^{T}(t) \ell^*(t)$  $\frac{\partial^2 \mathcal{H}}{\partial u^2} (*,t) = \mathcal{R}(t).$ Since His quadratic in & and 22x/du2 is positive definite (because R(t) is positive definite by assumption), the control  $\mathcal{L}^{*}(t) = -\mathcal{R}^{-1}(t) \mathcal{R}^{T}(t) \mathcal{R}^{*}(t)$ does (globally) minimize X. 5-9 (a) Differentiating p\*(t)=K(t) 然村) \*\*(t)=K(t) x\*(t)+K(t) x\*(t), (I) $\dot{x}^*(t) = A(t) \dot{x}^*(t) + B(t) \dot{x}^*(t)$  $= \underline{\mathbb{A}}(t) \underline{\mathbb{X}}^{*}(t) - \underline{\mathbb{B}}(t) \underline{\mathbb{R}}^{-1}(t) \underline{\mathbb{B}}^{\mathsf{T}}(t) \mathcal{L}^{*}(t).$  5-9 (cont.) Thus,

 $\dot{\hat{x}}^*(t) = \left[ \underline{A}(t) - \underline{B}(t) \underline{R}^{-1}(t) \underline{B}^{T}(t) \underline{K}(t) \right] \underline{X}^*(t),$ 

and

 $\dot{\mathcal{L}}^*(t) = -\mathcal{Q}(t) \times^*(t) - \mathcal{A}^T(t) \mathcal{L}^*(t)$   $= \left[ -\mathcal{Q}(t) - \mathcal{A}^T(t) \mathcal{L}(t) \right] \times^*(t).$ 

Substituting for  $\dot{x}^*(t)$  and  $\dot{p}^*(t)$  in (I) gives the result

 $\left[-Q(t)-A^{T}(t)K(t)\right]\chi^{*}(t)=\left[\dot{K}(t)+\dot{K}(t)A(t)\right]$ 

一点(t)及(t)及"(t)及"(t)及(t)及类(t).

Since this equation must hold for all  $X^*(t)$ , we have

 $\mathring{K}(t) = -K(t)A(t) - A^{T}(t)K(t) - Q(t)$ 

+ K(+)B(+)R-1(+)B(+)K(+)

and

 $\mathcal{Z}^{*}(t_f) = \underbrace{K}(t_f) \underbrace{\times}^{*}(t_f) = \underbrace{H} \underbrace{\times}^{*}(t_f),$ 

(b) Taking the transpose of the Riccati equation gives

5-9 (cont.)

92

 $\begin{bmatrix} \mathring{\mathbf{K}} \end{bmatrix}^{\mathsf{T}} = \begin{bmatrix} - \mathring{\mathbf{K}} \mathring{\mathbf{A}} - \mathring{\mathbf{A}}^{\mathsf{T}} \mathring{\mathbf{K}} - \mathring{\mathbf{Q}} + \mathring{\mathbf{K}} \mathring{\mathbf{B}} \mathring{\mathbf{R}}^{\mathsf{T}} \mathring{\mathbf{B}}^{\mathsf{T}} \mathring{\mathbf{K}} \end{bmatrix}^{\mathsf{T}}$ 

(the argument t has been omitted for simplicity). By using the matrix identity [CD] = DTCT, we have

 $\begin{bmatrix} \mathring{\mathbf{k}} \end{bmatrix}^{\mathsf{T}} = -\mathring{\mathbf{A}}^{\mathsf{T}} \mathring{\mathbf{k}} - \mathring{\mathbf{k}}^{\mathsf{T}} \mathring{\mathbf{A}} - \mathring{\mathbf{Q}}^{\mathsf{T}} + \mathring{\mathbf{k}}^{\mathsf{T}} \mathring{\mathbf{R}} \begin{bmatrix} \mathring{\mathbf{k}}^{\mathsf{T}} \end{bmatrix}^{\mathsf{T}} \mathring{\mathbf{B}}^{\mathsf{T}} \mathring{\mathbf{k}}^{\mathsf{T}} (\mathring{\mathbf{m}})$ 

But Q is symmetric so  $Q^T = Q$ ; R is symmetric, so  $R^{-1}$  is symmetric and  $[R^{-1}]^T = R^{-1}$ . Therefore,

[i] = -ATKT-KTA-Q+KTBR-BTKT.AI)

We know that [d (K(t))] = d [KT(t)]

i.e., that operations of transposition and differentiation are commutative; hence, the left side of (II) can be replaced by dt [KT]. The boundary condition for (II) is KT(tf) = HT=H. In (II) let KT=M,

then

 $\frac{\mathcal{N}}{\mathcal{M}} = -A^{T}M - MA - Q + MBR^{-1}B^{T}M$ and

以(年)= 出.

M(t) and K(t) satisfy the same differential equation with the same boundary conditions; therefore, since the solution is unique, we conclude that  $M(t) \triangleq K^{T}(t) = K(t)$ .

Since K is symmetric we need solve only for the elements of K which lie on or above the main diagonal. The number of terms involved is 1+2+3+ ... + n. This summation is formed from the elements of an arithmetic progression. The sum is equal to n(n+1)/2.

(c) If  $X(t_f) = Q / X(t_f)$  does not exist (contains infinite-valued

5-9 (cont.)

elements), so modifications must be made. For two ideas on this

subject, see the IEEE Trans. on Automatic Control June 1967, p. 303 and p. 323.

5-10

From Eq. (5.2-12)

 $\chi^*(t_f) = \varphi_{II}(t_f, t) \chi^*(t) + \varphi_{I2} \chi^*(t).$ 

With  $x^*(t_f) = 0$  we obtain

 $2^{*}(t) = -\varphi_{12}^{-1}(t_1, t) \mathcal{L}_{11}(t_2, t) \times^{*}(t).$ 

Since

$$\mathcal{L}^*(t) = -\mathcal{R}^{-1}(t)\mathcal{B}^{T}(t)\mathcal{R}^*(t),$$

 $U^{*}(t) = R^{-1}(t) B^{T}(t) \mathcal{L}_{12}^{-1}(t_{f_{1}}t) \mathcal{L}_{11}(t_{f_{2}}t) X(t)$ 

(valid for all X\*(t)).

5-11 (a) The state-costate equations

$$\begin{bmatrix} \dot{\chi}^{*}(t) \\ \dot{p}^{*}(t) \end{bmatrix} = \begin{bmatrix} -1 & -1 \\ -3 & 1 \end{bmatrix} \begin{bmatrix} \chi^{*}(t) \\ p^{*}(t) \end{bmatrix}$$

have the transition matrix

$$\varphi(t) = \begin{bmatrix} \frac{3}{4} e^{-2t} + \frac{1}{4} e^{2t} & \frac{1}{4} e^{-2t} - \frac{1}{4} e^{2t} \\ \frac{3}{4} e^{-2t} - \frac{3}{4} e^{2t} & \frac{1}{4} e^{-2t} + \frac{3}{4} e^{2t} \end{bmatrix}.$$

From the solution of Problem 5-10  $u^*(t) = 3 e^{-2(t_f - t)} + e^{2(t_f - t)}$  $e^{-2(t_{\varphi}-t)}$   $= e^{2(t_{\varphi}-t)}$   $\times (t)$ .

(b) With X(1) free, using Eq. (5.2-14)

$$p^*(t) = [\varphi_{zz}(t_f - t)]^{-1} [-\varphi_{z}(t_f - t)] x^*(t)$$

thus,  

$$u^{*}(t) = \frac{3\left[e^{-2(t_{f}-t)} - e^{2(t_{f}-t)}\right]}{e^{-2(t_{f}-t)} + 3e^{2(t_{f}-t)}} \propto (t).$$

5-12

(a) The form of the solution for x\*(t), p\*(t) is the same as given by Eq. (5.1-68), The boundary condition equations are  $x_1^*(2) + 5 x_2^*(2) = 15$ (T)

5-12 (cont.)

and from entry 3 of Table 5-1

$$\begin{bmatrix} x_1^*(2)-5 \\ x_2^*(2)-2 \end{bmatrix} - x_1^*(2) = d \begin{bmatrix} 1 \\ 5 \end{bmatrix},$$

therefore,
$$p_1^*(2) = x_1^*(2) - 5 - d \qquad \text{(II)}$$

$$p_2^*(2) = x_2^*(2) - 2 - 5d. \qquad \text{(III)}$$

From (II)
$$d = x_1^*(2) - 5 - p_1^*(2),$$

hence
$$p_2^*(2) = x_2^*(2) - 2 \cdot 5 \begin{bmatrix} x_1^*(2) - 5 - p_1^*(2) \end{bmatrix},$$

or
$$p_2^*(2) = x_2^*(2) - 5x_1^*(2) + 5p_1^*(2) + 23. \text{(IIIa)}$$

As in Example 5.1-1  $c_1 = c_2 = o_1^*$ 
to find  $c_3$  and  $c_4$  we substitute from Eq. (5.1-69) (with  $t_1 = 2 = t$ )
into (I) and (IIIa) and solve for  $c_3$  and  $c_4$ ; the result is
$$c_3 = -2.598 \qquad c_4 = -2.637$$

 $u^*(t) = -p_2^*(t) = -c_3 + c_3 \in t - c_4 \in t.$ 

5-12 (cont.)

97

(b) The cost of control is

 $\int_{0}^{\frac{1}{2}} u^{*2}(1) dt = \frac{1}{2} \left[ c_{3}^{2} t - 2c_{3} c_{5} e^{t} + \frac{1}{2} c_{5}^{2} e^{2t} \right]_{0}^{2}$ (where  $c_{5} = c_{3} - c_{4}$ ).

 $\int_{0}^{2} \pm u^{*2}(t) dt = c_{3}^{2} - c_{3}c_{5} e^{2} + c_{3}c_{5} + 4 c_{5}^{*}e^{4} - 4 c_{5}^{2}.$ 

Substituting the values found for coand ca gives

 $J_u = 16.58$  (IV) Part (a) of Example 5.1-1  $J_u = 3.55$  (V) Part (b) of Example 5.1-1  $J_u = 7.42$  (VI) Part (a) of Problem 5-12,

where  $J_u$  denotes the cost of control.

The point is that in (IV) above the final state is most restricted,  $\chi(2)$  must be exactly [5 2]; thus, the required control energy is largest. In (V) above we only require that  $\chi(2)$  be "close" to [5 2]. Finally, in (VI),  $\chi(2)$ 

5-12 (cont.) is to be "close" to [s z] and lie on the line x,(2)+5x(2) = 15; this case is less restrictive than (IV) (hence smaller Ju for VI) but more restrictive than (v). 5-13  $\mathcal{H} = -x(t) - . \, (p(t) \times (t) + p(t) \, u(t)$ from which  $p^*(t) = 1 + 0.1 p^*(t)$ . This differential equation has a solution of the form  $p^*(t) = c_1 + c_2 e^{-t}$ . substituting this solution in the D.E. and equating coefficients of like powers of E gives c1=-10 Since the final state is free and there is no term in  $x(t_f)$ p\* (100)=0 ⇒ Cz = 10 € -10 j thus, p\*(t) = -10+106-.1 (100-t)

5-13 (cont.)

Minimization of X with respect to

u gives

 $u^*(t) = \begin{cases} 0 & \text{for } p^*(t) > 0 \\ M & \text{for } p^*(t) < 0. \end{cases}$ 

The solution found above for p\*(t) is less than zero for all te [0,100]; hence,

u\*(t) = M , t & [0,100].

(b) Let  $\dot{x}_2(t) \triangleq U(t)$ ,  $\dot{x}_2(0) = 0$ ,  $\dot{x}_2(100) = K$   $\dot{x}_2(t) = -\dot{x}_1(t) - i p_i(t)\dot{x}_i(t) + p_i(t) u(t) + p_2(t)u(t)$ , where it is easily shown that  $p_2^*(t)$  is a constant. The D.E. and solution for  $p_i^*(t)$  are as found in part (a), that is,  $p_i^*(t) = -i0 + i0e^{-i1(100-t)}$ .

Minimizing  $\mathcal{L}$  with respect to u gives  $u*(t) = \begin{cases} 0 & \text{for } p_i^*(t) + p_i^*(t) > 0 \\ M & \text{for } p_i^*(t) + p_i^*(t) < 0, \end{cases}$ 

5-13 (cont.)  $p^*(t) + f_2^*(t) = -10 + 10 e^{-1/(100-t)} + c_3$ .

Examining the possible forms for  $p^*(t) + p_2^*(t)$  we see that the sign of  $p^*(t) + p_2^*(t)$  can change at most once; therefore,  $u^*(t)$  must be of one of the following forms

 $u^*(t) = \{M\}, \{o\}, \{M, o\}, \{o, M\}.$ (I) (II) (III) (III)

(III) is impossible because pi\*(t) + pi\*(t) cannot change from + to -.

(II) is impossible because it will not satisfy  $\int_0^{\infty} \hat{u}(t) dt = K$  unless K=0 (a trivial case).

(I) is not possible unless fondt = k, a very special circumstance -- we will assume that this is not the case, which means that

 $u^*(t) = \begin{cases} M, & t \in [0, t_i] \\ 0, & t \in (t_i, 100] \end{cases}.$ 

Since  $\int_0^{t_1} Mdt = K$ ,  $t_1 = K/M$ .

5-13 (cont.)

101

(c)  $\mathcal{H} = -.1p_1(t)x_1(t) + [p_1(t) + p_2(t)]u(t)$  $p_i^*(t) = \cdot |p_i^*(t)| : p_i^*(t) = c_i e^{-it}$ P,\*(100)=-1 ⇒  $c_1 = -e^{-1/6}$  $p^*(t) = -E^{-1/(100-t)}, p^*(t) = c_2.$ we again find that p,\*(t)+p,\*(t) can change sign at most once, and that if a sign change occurs it is from t to -. Using the same reasoning as in part (b), we rule out all possibilities except  $u^*(t) = \begin{cases} 0, & t \in [0, 100 - k/M) \\ M, & t \in [100 - k/M, 100]. \end{cases}$ 

5-14

(a) The Riccati equation with k=0is  $0 = -2a k - 2g + \frac{k^2}{2r}$   $k^2 - 4ar k - 4gr = 0$ ;
the solution is

k= 2ar ± /422 +4gr.

The feedback gain is

f = -a 7 Vaz+g/r.

The D.E. for the closed-loop system is

 $\dot{x}(t) = a \times (t) + [-a \mp \sqrt{a^2 + g/r}] \times (t)$   $= \mp \sqrt{a^2 + g/r} \times (t).$ 

The - sign is the optimal solution; the + sign gives an unstable system.

Jw splane

Jw s plane

g/r-rap g/r=0

locus of pole of closed-loop system

(b) Expanding the terms in the Riccati eq. with k(t) = 0 gives  $k_{12}^{2} + 16 k_{12} - 80 = 0$  (I)  $k_{12} k_{22} + 8 k_{22} + 8 k_{12} - 2k_{11} = 0$  (II)

5-14 (conti)  $k_{12}^{2} + 16k_{12} - 4k_{12} - 20 = 0$ . (III)

Noting that  $U^*(t) = -R^{-1}B^T h^* \chi(t)$ , and that  $-R^{-1}B^T k \triangleq E = [-\frac{k_{12}}{2} - \frac{k_{22}}{2}]$ , it is necessary only to solve for  $k_{12}$  and  $k_{22}$ .

From (I)  $k_{12} = -8 \pm \sqrt{64 + 80}' = +4, -20.$ From (III)

k22 +16 k22 -20 + { -167 = 0

kzz = -8 ± (64+20+[16] = -8+[[16]]

 $= \frac{+2,-18}{k_{12}=+4} \frac{-6,-10}{k_{12}=-20}$ 

The poles of the closed-loop system are the roots of det[sI-A-BE] = | s -1 | 4+k= statker

= 52+45+ k22 s+4+ k12.

For stability it is necessary and

5-14 (cont.) sufficient that

 $4 + \frac{k_{12}}{2} > 0 \implies k_{12} > -8$ and  $4 + \frac{k_{12}}{2} > 0 \implies k_{12} > -8$ 

" k12 = +4, k22 = +2.

The characteristic equation for the closed-loop system is

 $5^2 + 55 + 6 = (5+3)(5+2)$ 

>> poles at 5=-3,-2.

The poles of the open-loop system are the roots of det [SI-A] = | \$ -1 | = 52+45+4

= (5+2)(5+2).

The optimal controller moves one of the poles to -3.

5-15 Expanding the Riccati equation with  $\dot{K}(t)=0$  gives

$$0 = -2 + \frac{1}{2} k_{12}^{2} \qquad (\pm)$$

$$0 = k_{12} - k_{11} + \frac{1}{2} k_{12} k_{22} \quad (II)$$

$$0 = 2k_{22} - 2k_{12} - 2 + \frac{1}{2}k_{22}^{2}. (III)$$

Since the feedback gain matrix E is

$$E = -R^{-1}B^{T}K = -\frac{1}{2}[k_{12} \quad k_{22}],$$

we only need to solve for  $k_{12}$  and  $k_{22}$ . From (I),  $k_{12}=\pm 2$ ; substituting this into (III) yields

$$k_{22}^{2} + 4k_{22} \mp 8 - 4 = 0$$

$$k_{22} = -2 \pm \sqrt{4 \pm 8 + 4} = -2 \pm \begin{Bmatrix} 4 \\ 0 \end{Bmatrix}$$
$$= \begin{Bmatrix} +2, -6 \\ -2, -2 \end{Bmatrix}.$$

The poles of the closed-loop system are the roots of  $\det \left[ SI - A - E \right] = S^2 + S + \frac{k_{22}}{2}S + \frac{k_{12}}{2}.$  For stability it is necessary

5-15 (cont.)

and sufficient that  $1 + \frac{k_{22}}{2} > 0 \implies k_{22} > -2$ and

 $\frac{k_{12}}{2}$  >0

therefore,  $k_{12}=+2$  and  $k_{22}=+2$ . Also,  $E=\begin{bmatrix}-1 & -i\end{bmatrix}$ , or  $U^*(t)=-x_1(t)-x_2(t)$ .

5-16

(a) Replacing y by  $\mathcal{L}$  in  $\mathcal{J}$  gives  $\mathcal{J} = \frac{1}{2} \chi^{T}(t_{5}) \mathcal{L}(t_{5}) \mathcal{H} \mathcal{L}(t_{5}) \chi(t_{5}) + \frac{1}{2} \int_{t_{0}}^{t_{5}} \chi^{T}(t_{5}) \mathcal{L}(t_{5}) \chi(t_{5}) \chi$ 

This is the same form as the performance measure for the linear regulator problem with H replaced by

 $\cancel{H}' = \cancel{c}^{T}(t_{4}) \cancel{H} \cancel{c}(t_{4})$ 

5-16 (cont.) and Q(t) replaced by  $Q'(t) = C^{T}(t)Q(t)C(t)$ .

Notice that symmetry of H
implies that H' is symmetric;
similarly Q(t) symmetric => Q'(t) is
symmetric. It is not difficult
to show that since H and Q
are positive semi-definite, H' and
Q' are also; hence, the problem
has been reduced to a linear
(state) regulator problem.

(b) The optimal control law follows directly from the results given in Section 5.2, i.e.

$$\mathcal{L}^{*}(t) = -\mathcal{R}^{-1}(t) \mathcal{B}^{T}(t) \mathcal{K}(t) \mathcal{L}(t)$$

Where K is the solution of the Riccati equation with Q replaced by Q' and with the boundary condition K(tx) = H'.

Notice that the optimal control law is linear feedback of the

system states. The assumption that the system is completely observable ensures that the state vector can be computed from knowledge of the system outputs.

5-17 (a) Let x(t) = x(t)-r(t), then  $J = \frac{1}{2} \int \left[ g \tilde{\chi}^2(t) + u^2(t) \right] dt.$ 

The D.E. for  $\widetilde{\chi}(t)$  is

 $\tilde{\chi}(t) = \dot{\chi}(t) - \dot{\hat{r}}(t) = -\chi(t) + u(t) - [-d e^{-t}]$ = - x(t) +u(t) +r(t)

 $\widetilde{\chi}(t) = -\widetilde{\chi}(t) + u(t)$ .

Thus, we have a linear regulator problem. Notice that the optimal control law is

 $u^*(t) = f(t) \hat{\chi}(t) = f(t) \left[ \chi(t) - r(t) \right],$ that is, linear feedback of the error between the actual and desired state.

(b) Defining the system states as Suggested gives

$$x_{1}(t) = y(t) - r(t)$$
,  $x_{2}(t) = \dot{y}(t) - \dot{r}(t)$ , ...,  $x_{n}(t) = \frac{d^{n-1}}{dt^{n-1}} [y(t) - r(t)]$ , which

makes

$$J = \frac{1}{2} \int_{0}^{t} [g \times_{1}^{2}(t) + u^{2}(t)] dt.$$

The state equations become  $\dot{x}_{1}(t) = \dot{y}(t) - \dot{r}(t) = x_{2}(t)$ 

$$\dot{\chi}_z(t) = \chi_3(t)$$

$$\dot{\dot{x}}_{n}(t) = \frac{d^{n}}{dt^{n}} \dot{y}(t) - \frac{d^{n}}{dt^{n}} \dot{r}(t).$$

Because of the D.E. Entisfied by y(t) and r(t), the last equation becomes

$$\dot{x}_{n}(t) = -a_{n-1} \frac{d^{n-1}}{dt^{n-1}} y(t) - \dots - a_{0} y(t) + u(t) - \left\{ -a_{n-1} \frac{d^{n-1}}{dt^{n-1}} r(t) - \dots - a_{0} r(t) \right\}$$

$$= -a_{n-1} \frac{d^{n-1}}{dt^{n-1}} \left[ y(t) - r(t) \right] - ... - a_0 \left[ y(t) - r(t) \right] + u(t)$$

$$= -a_{n-1} x_n(t) - \dots - a_0 x_i(t) + u(t).$$

Hence, the problem has been reduced to one of the linear regulator type.

5-19

(a) Let t, be the time required for the missile required to reach b,

 $a + .1 t_1^3 = b \implies t_1 = (10[b-a])^{1/3}$ 

(b) For interception to occur at t=tz

 $a + .1t_z^3 = b_1$  (x) and

 $\frac{1}{2}t_2^2 = b_1 \cdot (II)$ 

Solving (II) for  $t_z$  gives  $t_z = (2b_i)^{1/2}$ . Substituting this in (I) yields

 $a + .1 (26)^{3/2} = b_1$ .

Rearranging and squaring gives

8bi -100bi +200ab, -100a2 = 0. (III)
(c) We already know from the text example that interception can occur only if a ≤ 1.85. To determine the values of a and b for which interception is accomplished before the missile reaches b, we solve (III) for a

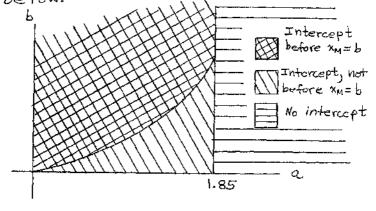

and b. Doing this gives

 $a = b_1 \pm \sqrt{.08 b_1^3}$ .

A few tabulated values are shown below(only feasible solutions are included).

b<sub>1</sub> a.
0. 0.
0.5 0.4
1.0 0.72
2.0 1.2
3.0 1.53
4.0 1.74
5.0 1.84
5.55 1.85

The required diagram is shown below.

 $\mathcal{H} = 1 + \rho_1(t) \times_z(t) + \rho_z(t) u_1(t) + \rho_z(t) u_z(t)$ 

 $p^*(t) = 0 \Rightarrow p^*(t) = c_1 \quad (a \quad constant)$ 

 $p_2^*(t) = -p_1^*(t) = -c_1 \Rightarrow p_2^*(t) = -c_1 t + c_2$ .

Minimizing X with respect to W(1) gives

$$u_{+}^{*}(t) = \begin{cases} 0, & \rho_{2}^{*}(t) > 0 \\ M, & \rho_{2}^{*}(t) < 0 \end{cases}$$

$$u_{z}^{*}(t) = \begin{cases} 0 & \rho_{z}^{*}(t) > 0 \\ -M & \rho_{z}^{*}(t) < 0 \end{cases},$$

Since p2\*(t) can change sign at most once, the optimal controls

have the possible forms

$$u_{*}^{*} = \{0, M\}, u_{2}^{*} = \{-M, 0\}$$
 (I)

$$u_{1}^{*} = \{M, 0\}, u_{2}^{*} = \{0, -M\}$$
 (IL)

$$u_{i}^{*}=\{0\}, u_{2}^{*}=\{-M\}$$
 (III)

$$u_{i}^{*} = \{+M\}, u_{2}^{*} = \{0\}. \quad (IV)$$

(IV) is eliminated because the boundary condition  $x_2(t_f) = 0$  could not be satisfied. (III) can be eliminated because of the constraint 05 x2(t) —

(I) can be eliminated for the same reason. If the braking system of the car is mechanical, (I) and (III) could also be eliminated because there would be no decelerating force without a velocity having been acquired and (I) and (III) would not follow velocity acquisition with braking. For braking by deflection of thrusting gases, (I) and (III) would be eliminated by the constraint 05 x2(t).

This leaves only (II), so

$$u_1^*(t) = \begin{cases} M, & t \in [t_0, t_1] \\ 0, & t \in (t_1, t_1] \end{cases}$$

$$U_2^*(t) = \begin{cases} 0, & t \in [t_0, t_i] \\ -M, & t \in [t_i, t_i] \end{cases}$$

t, is the time where switching occurs (p\*(t,)=0). To find t, we note that

$$x_{2}(t_{1}) = 0 + \int_{t_{0}}^{t_{1}} Mdt = M(t_{1} - t_{0})$$

an d

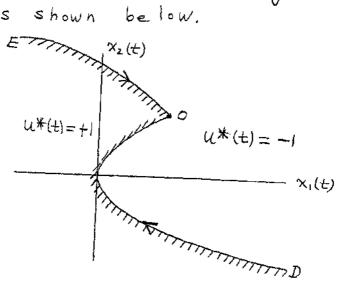

$$x_{2}(t_{f}) = 0 = x_{2}(t_{i}) + \int_{t_{i}}^{t_{f}} -Mdt$$
  

$$= M(t_{i}-t_{0}) - M(t_{f}-t_{i})$$

$$2Mt_{i} = M(t_{f}+t_{0}), t_{i} = \frac{t_{0}+t_{f}}{2}.$$

5-21

The optimal trajectories must be composed of segments of the parabolas shown in Fig. 5-20 and must intersect at the point  $X = [z z]^T$ . The switching curve is shown below.

To the left of the curve E-O-D the optimal control is u\*(t) = +1; to the right of E-O-D u\*(t) = -1.

To find the expression for E-0-D we use Egs. (5.4-39) and (5.4-40). From (5.4-39)

 $2 = \frac{1}{2}(4) + c_5 \implies c_5 = 0$ .

From (5.4-40)

 $2 = -\frac{1}{2}(4) + C_6 \implies C_6 = 4$ .

Hence the equation of E-O-D is

 $\chi_1(t) = \frac{1}{2} \chi_2^2(t)$  ,  $\chi_2(t) \leq 2$ 

 $\chi_1(t) = -\frac{1}{2} \chi_2^2(t) + 4, \quad \chi_2(t) \geq 2.$ 

5-22

Since part (b) can be done as easily a part (a), we will show the solution for (b) only.

 $\mathcal{H} = 1 + p_1(t) \times_1(t) + a_1 p_1(t) u(t) + a_2 p_2(t) \times_2(t) + a_2 p_2(t) u(t)$ 

=  $1 + a_1 p_1(t) x_1(t) + a_2 p_2(t) x_2(t)$ +  $[a_1 p_1(t) + a_2 p_2(t)] u(t)$ . Minimizing \* with respect to u gives (-1, a, p,\*(t) + a2 p2\*(t) > 0

$$u^{*}(t) = \begin{cases} -1, & a_{1}, p_{1}^{*}(t) + a_{2}, p_{2}^{*}(t) > 0 \\ +1, & a_{1}, p_{1}^{*}(t) + a_{2}, p_{2}^{*}(t) < 0 \end{cases}$$
Undetermined for  $a_{1}p_{1}^{*}(t) + a_{2}p_{2}^{*}(t) = 0$ .

The costate equations are  $\dot{p}_{1}^{*}(t) = -\frac{\partial \mathcal{K}}{\partial x_{1}}(*,t) = -a_{1}p_{2}^{*}(t)$   $\dot{p}_{2}^{*}(t) = -\frac{\partial \mathcal{K}}{\partial x_{2}}(*,t) = -a_{2}p_{2}^{*}(t)$ ;
hence,

 $p_{z}^{*}(t) = c_{z} \in -a_{z}t$ ,  $p_{z}^{*}(t) = c_{z} \in -a_{z}t$ .

we note that a singular interval cannot exist because

a,p\*(t) +azp\*(t) can only be zero for a finite time interval if c,=cz=0. But if  $c_1=c_2=0$ ,  $p_1*(t)=p_2*(t)=0$  for all  $t\in [t_0,t_f]$ , and this implies that  $\mathcal{X}(*,t)=1$  for  $t\in [t_0,t_f]$ . Since this is a free final time problem with  $\mathcal{X}(*,t)=0$  not explicitly dependent on t, it is necessary that  $\mathcal{X}(*,t)=0$ ,  $t\in [t_0,t_f]$ .

Hence, a,p,\*(t)+a2 p2\*(t) cannot be zero for a finite time interval. The possible forms for

app\*(t) +azp\*(t) = a, c, € -a, t +azcz € -azt = f(t)
are shown below.

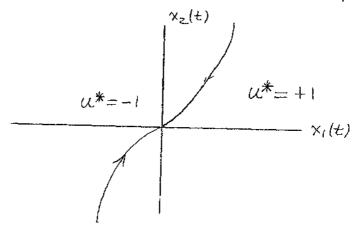

we see that the optimal control can switch at most once -- this also follows from Theorem 5.4-3; hence, the possible forms for the optimal controls are u\*= {+1}, {-1}, {-1}, {-1}, or {+1,-1}.

5-22 (cont.) Integrating the state equations with u(t) = ±1 gives  $x_1(t) = \mp 1 + c_3 \in a_1(t-t_F)$ ,  $x_2(t) = \mp 1 + c_4 \in a_2(t-t_F)$ At  $t = t_f \quad x_i(t_f) = x_z(t_f) = 0$  $\Rightarrow$   $c_3 = \pm 1$  ,  $c_4 = \pm 1$  $\chi_{I}(t) = \mp I \pm e^{a_{I}(t-t_{F})} \quad (\pm)$   $\chi_{L}(t) = \mp I \pm e^{a_{L}(t-t_{F})} \quad (\pm)$ Solving for (t-tf) in (I) yields  $t-t_f=\frac{1}{a_1}\ln\left(\pm\chi_1(t)+1\right).$ Substituting this into (II) gives  $x_2(t) = \mp 1 \pm \epsilon \stackrel{a_2}{a_i} ln(\pm x_i(t) + i)$  $=\mp1\pm\in ln(\pm\chi_{1}(\pm)+1)^{\alpha_{2}/\alpha_{1}}$ 

i.  $x_2(t) = \mp 1 \pm (\pm x_1(t) + 1)^{a_2/a_1}$ .

The upper signs correspond to  $u*(t) = \pm 1$ . This is the equation of the switching curve: the curve and the optimal control law are shown below.

In this case the regions where u\*=+1 and u\*=-1 can be determined (as in Example 5.4-4) by examining a few trajectories which begin off the switching curve and have  $u=\pm 1$ .

5-23

(a) Let the states be  $x_1 \triangleq x_1, x_2 \triangleq \hat{x}_1$   $x_3 \triangleq y$ ,  $x_4 \triangleq \hat{y}(t)$ , and the control is  $u \triangleq \beta$ . The state equations are  $\hat{x}_1(t) = x_2(t)$   $\hat{x}_2(t) = \frac{T}{M} \cos u(t)$   $\hat{x}_3(t) = x_4(t)$   $\hat{x}_4(t) = \frac{T}{M} \sin u(t)$ .

5-23 (cont.)

(b)  $\mathcal{H} = 1 + p_1(t) \times_2(t) + p_2(t) \left[ \frac{1}{M} \right] \cos u(t) + p_3(t) \times_4(t) + p_4(t) \left[ \frac{1}{M} \right] \sin u(t)$ .

The costate equations are

 $\dot{P}_i^*(t) = 0 \Rightarrow P_i^*(t) = c_i$ 

 $\dot{p}_{z}^{*}(t) = -p_{i}^{*}(t) \Rightarrow p_{i}^{*}(t) = -c_{i}t + c_{z}$ 

 $p_3^*(t) = 0 \implies p_3^*(t) = c_3$ 

1/4\*(t) = -P3\*(t) => P4\*(t)=-C3t+C4.

The specified final states are

 $x_{2}^{*}(t_{2}) = V$ ,  $x_{3}^{*}(t_{2}) = D$ ,  $x_{4}^{*}(t_{2}) = 0$ .

Since the final state  $x_i(t_f)$  is free and there is no term in J involving  $x_i(t_f)$ ,  $p_i^*(t_f) = 0$ . The other

boundary condition is \((\*,t\_f)=0.

(c) The control which minimizes X is found from

$$\frac{\partial \mathcal{L}}{\partial u}(*,t) = 0 = \frac{1}{M} \left\{ p_{2}^{*}(t) \left[ -\sin u^{*}(t) \right] + p_{4}^{*}(t) \left[ \cos u^{*}(t) \right] \right\}$$

$$\Rightarrow \frac{\sin u^*(t)}{\cos u^*(t)} = \frac{p_*^*(t)}{p_*^*(t)}$$

5-23 (cont) 121

or  $\sin u^*(t) = \frac{p_4^*(t)}{\left[p_2^{*2}(t) + p_4^{*2}(t)\right]^{1/2}}$ 

 $\cos u^*(t) = \frac{p_2^*(t)}{\left[p_2^{*2}(t) + p_2^{*2}(t)\right]^{1/2}}$ 

From (b), since  $p^*(t_f)=0$ ,  $c_i=0$ ;
this implies that  $p_2^*(t)=c_2$  (a const.).
To determine  $c_2,c_3$  and  $c_4$  we would have to substitute for  $u^*(t)$  in the state equations (in terms of  $c_2,c_3,c_4$ ), integrate and set

 $x_2^*(t_f) = V$ ,  $x_3^*(t_f) = D$ ,  $x_4^*(t_f) = 0$ . Then we must solve these equations (which will be nonlinear algebraic equations) to obtain  $c_2, c_3$  and  $c_4$ .

(d) Now J = -x1(tq). The costate equations and the optimal control (in terms of px(t) and px(t)) will be as found earlier. The boundary conditions are

 $x_*^*(t_f) = D \quad p_*(t_f) = -1 \cdot p_*^*(t_f) = p_*^*(t_f) = 0$ 

With these boundary conditions  $c_1 = -1$ ,  $c_2 = -t_f$ ,  $-c_3 t_f + c_4 = 0$ .

The procedure to solve for C3 (or C4), since to is known, is to substitute for u\*(t) in the state equations (in terms of cs) integrate, xx(tq)=D,

and solve for C3.

5-24

(a) The solution of the state

equation is

 $x(t) = \varphi(t) \left[ x_0 + \int_{-\tau}^{t} \varphi(-\tau) u(\tau) d\tau \right]$ 

where  $\varphi(t) = E^{2t}$ . Suppose that a control is found which makes x(T)=0,

 $0 = x_0 + \int \varphi(-\tau) u(\tau) d\tau,$ 

$$-x_0 = \int_0^T \varphi(-z) \, u(z) \, dz$$

which implies that

$$|x_0| = \left| \int_0^T \varphi(-\tau) \, u(\tau) \, d\tau \right|.$$

But,

5-24 (cont.)  $\left|\int_{0}^{T} \varphi(-\tau) u(\tau) d\tau\right| \leq \int_{0}^{T} |\varphi(-\tau)| |u(\tau)| d\tau,$ and since lu(t) 151, |xo| ≤ [ |φ(-τ)| dt. Substituting  $e^{-2z}$  for  $\varphi(-z)$  and integrating gives

 $|x_0| \leq \frac{1}{2} \left[ 1 - \epsilon^{-2T} \right]$ 

 $2|x_0|-1 \le -e^{-2T} \implies e^{-2T} \le |-2|x_0|.$ Since E-2T > 0 for all finite T, this can only be satisfied if

1x0/</2

An alternative approach is the following:

Assume that xo < 0. By inspection of the state equation it is clear that if x is to be transferred to gero, then it must be possible to make x(t) > 0. In fact, if  $\dot{x}(0) < 0$  then x(t) will be getting more negative; hence,

5-24 (cont.)

124

if the control cannot make  $\dot{x}(0)>0$ , the control cannot bring the system to the origin. Therefore,  $\dot{x}(0)>0$ , or  $0<2x_0+u(0)$ , and this implies that

-2x0 < U(0).

Since Xo < 0, we have

-2xo < 1 or xo > -1/z. Similar reasoning for xo > 0 leads to the conclusion that xo < 1/z; therefore,

-1/2 < x0 < 1/2 , or 1x0 1 < 1/2 .

Both solutions indicate that if

there is no admissible control which transfers the system to the origin.

(b) We now have n uncoupled state equations which have the solution  $x_i(t) = e^{a_i t} \left[ x_{io} + \int_0^t e^{-a_i z} b_i \, u(z) \, d\tau \right],$ 

125

for i=1,2,...,n. Let us suppose that there is a control which makes  $x_i(\tau)=0$ , i=1,2,...,n, then

$$0 = x_{i_0} + \int_0^T e^{-a_i \tau} b_i u(\tau) d\tau, \text{ or}$$

$$|x_{io}| = \left| \int_{0}^{T} e^{-ai\tau} b_{i} u(\tau) d\tau \right|$$

$$\leq \int_{0}^{T} \left| e^{-ai\tau} \right| \left| b_{i} \right| \left| u(\tau) \right| d\tau.$$

Since  $|u(t)| \le 1$ ,  $e^{-ai\tau} \ge 0$ ,  $|x_{io}| \le \iint_{\infty}^{T} e^{-a_i \tau} d\tau \left[ |b_i| \right]$ , or

$$|\chi_{i_0}| \leq -\frac{|b_i|}{a_i} \left[ e^{-a_i \tau} - 1 \right]$$
.

If ai <0, and T finite, this implies | xio| < \in . Now suppose that the largest ai is a and that ai> 0. In this case

$$\frac{a_1 | x_{10}|}{|b_1|} \leq 1 - \epsilon \quad \text{or}$$

$$\epsilon^{-a_1T} \leq 1 - \frac{a_1 | x_{10}|}{|b_1|}.$$

Since E-ait > 0 for all finite T, this implies that

ailxiol <1, or that only those initial states which satisfy

 $|x_{io}| < \frac{|b_i|}{a_i}$ 

can be brought to the origin.

In summary, if all of the eigenvalues (a,az,..., an) are negative, all initial states can be transferred to the origin; if a,az,..., a, are positive then initial states for which

 $|x_{i,0}| \ge \frac{|b_{i}|}{a_{i}}$  ,  $i = b_{i} \ge 1$ 

cannot be transferred to the origin.

5-25(a)  $\det [sI-A] = \det [s-1]$   $2 \quad s+2$ 

 $= S^2 + 2S + 2$ 

5-25 (cont.)  
The roots are 
$$S = -1 \pm JI$$
.  
(b)  $H = 1 + p_1(t) \times_2(t) - 2p_2(t) \times_1(t) - 2p_2(t) \times_2(t) + p_2(t) \cup U(t)$ .

Therefore, 
$$u^*(t) = \begin{cases} +1, & p_2^*(t) < 0 \\ -1, & p_2^*(t) > 0 \end{cases}$$
 undetermined, 
$$p_2^*(t) = 0.$$

To show that a singular interval, i.e. an interval  $[t_1,t_2]$  such that  $p_2^*(t)=0$ , cannot exist, we observe that it is necessary that  $\mathcal{H}(t,t)=0$  for  $t\in [t_0,t_f]$ . The costate equations are  $p_1^*(t)=2p_2^*(t)$   $p_2^*(t)=-p_1^*(t)+2p_2^*(t)$ . If there is a singular interval,  $[t_1,t_2]$  such that  $p_2^*(t)=0$  for  $t\in [t_1,t_2]$ , then  $p_2^*(t)=0$  for

te[t,,tz]. But, if this is the

5-25 (cont.) case,  $p_1^*(t) = 0$  for  $t \in [t_1, t_2]$ (by inspection of the second costate equation). However, if  $p_2^*(t) = p_1^*(t) = 0$  for  $t \in [t_1, t_2]$ , then  $\mathcal{H}(*,t) = 1$  for  $t \in [t_1,t_2]$ . Since this violates a necessary condition for optimality, a singular interval cannot exist. If, therefore, an optimal control exists, it is bang-bang. (c) The eigenvalues for the costate system of equations are the roots of 52-25+2. These eigenvalues are  $\lambda_1 = 1 - J1$ ,  $\lambda_2 = 1 + J1$ . The transition matrix for the costate system is of the form  $\alpha_3 \in ^t \cos(t + \beta_3)$ [ a, E t cos(t+B,)  $\left[\alpha_2 e^{t} \cos(t+\beta_2) \quad \alpha_4 e^{t} \cos(t+\beta_4)\right],$ 

 $p_z^*(t) = p_i^*(0) \alpha_z e^t \cos(t + \beta_z)$ + P2\*(0) ×46 tcos (t+84).  $d_z$ ,  $d_4$ ,  $\beta_2$  and  $\beta_4$  are sonstants. Since the cosine terms are periodic,  $p_z^*(t)$  can change sign an unlimited number of times. 5-26

In the paper "Design of QuasiOptimal Minimum-Time Controllers",
which appeared in the IEEE Trans.

Automatic Control, vol. AC-11, No. 1,

Jan. 1966, F.w. Smith states that
the switching surface is given by  $x_1 = -\left[\begin{array}{c} x_3 \\ 3 \end{array}\right] + d \times_2 \times_3 + d \left(\begin{array}{c} x_3 \\ 2 \end{array}\right] - d \times_2$ 

where  $d = sign \left[ x_2 + \frac{x_3 |x_2|}{2} \right]$ .

Only the equations which differ from those in the example will be given.

(a) Let  $\chi_5(t) \triangleq M(t), u_2(t) \triangleq \dot{M}(t)$ 

 $\dot{x}_3(t) = \chi_4^2(t)/\chi_1(t) - g_0 R^2/\chi_1^2(t) - \frac{k u_2(t)}{\chi_2(t)} \sin u_1(t)$ 

 $\dot{x}_{4}(t) = -x_{3}(t)x_{4}(t)/x_{1}(t) - \frac{ku_{2}(t)}{x_{5}(t)} \cos u_{1}(t)$   $\dot{x}_{5}(t) = u_{2}(t)$ .

5-27 (cont.)
(b) 
$$p^*(t) = \frac{-k p_3^*(t) u_2^*(t)}{x_5^*(t)} \sin u_1^*(t)$$

$$- \frac{k p_4^*(t) u_2^*(t)}{x_5^*(t)} \cos u_1^*(t).$$

(c)

$$\frac{\partial \mathcal{L}}{\partial u_{1}}(*,t) = 0 = \frac{-k p_{3}^{*}(t) u_{2}^{*}(t)}{\chi_{5}^{*}(t)} \cos u_{1}^{*}(t)$$

$$+ \frac{k p_4^*(t) u_2^*(t)}{\chi_5^*(t)} \sin u_1^*(t).$$

+  $\frac{k p_4^*(t) u_2^*(t)}{\chi_5^*(t)}$  Sin  $u_1^*(t)$ .
To minimize  $\mathcal{H}$  with respect to uz, let

$$s(\chi(t), p(t), u_i(t)) \triangleq \frac{-k p_i(t)}{\chi_{c}(t)} \sin u_i(t)$$

$$-\frac{k\rho_4(t)}{\chi_s(t)}\cos u_i(t) + \rho_s(t).$$

Then

 $S(x^*(t), x^*(t), u_i^*(t)) u_z^*(t) \leq S(x^*(t), x^*(t), u_i(t)) u_z(t)$ which means that

$$u_{2}^{*}(t) = \begin{cases} -2 & s(x^{*}(t), p^{*}(t), u_{1}^{*}(t)) > 0 \\ 0 & s(x^{*}(t), p^{*}(t), u_{1}^{*}(t)) < 0 \\ \text{undetermined}, s(x^{*}(t), p^{*}(t), u_{1}^{*}(t)) = 0. \end{cases}$$

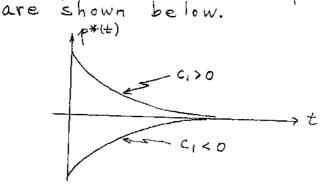

(d) Boundary conditions are the same as in Example 5.1-2 except

$$P_5^*(t_f) = 0$$

because M(tf) is free.

5-28

(a) 
$$t=1+p(t)ax(t)+p(t)u(t)$$
  
 $p^*(t)=-ap^*(t) \Longrightarrow p^*(t)=c, e^{-at}$   
The possible forms for  $p^*(t)$ 

Minimizing & with respect to u gives

$$u^{*}(t) = \begin{cases} -1, & p^{*}(t) > 0 \\ +1, & p^{*}(t) < 0 \\ & \text{undetermined}, & p^{*}(t) = 0. \end{cases}$$

It is easily shown that p\*(t)

cannot equal zero for a finite time interval; hence, a singular interval cannot exist.

The possible forms for the optimal control are

$$U = \{-1\}, \{1\}.$$

By inspection of the state equation it is clear that the time-optimal control law is

$$u^{*}(t) = \begin{cases} -1, & \chi(t) > 0 \\ +1, & \chi(t) < 0 \\ 0, & \chi(t) = 0 \end{cases}.$$

(b) H = |u(t)| + p(t) ax(t) + p(t) u(t).

The costate equations are the same as in part (a); hence, the costate solutions have the form shown previously.

Minimizing & with respect to u

$$u^{*}(t) = \begin{cases} -1, & 1 < p^{*}(t) \\ 0, & -1 < p^{*}(t) < 1 \\ +1, & p^{*}(t) < -1 \\ & \text{undetermined}, & p^{*}(t) = \pm 1. \end{cases}$$

5-28 (cont.)

/33

It can be shown that there are

no singular intervals.

Since p\*(t) cannot change sign,
the possible forms for the optimal control are.

The first three possibilities cannot be optimal because the system cannot reach the origin at the end of an interval of zero control. This is seen to be the case from the state equation with u(t) = 0; the solution has the forni

 $\chi(t) = \chi(t_i) \in a(t-t_i)$ 

and since a>0, |x(t)|>|x(ti)| for t>t, (the system moves further from the origin when u=0). Hence, by inspection the optimal control law 15

 $u^*(t) = \begin{cases} -1, & \text{for } x(t) > 0 \\ +1, & \text{for } x(t) < 0 \\ 0, & \text{for } x(t) = 0, \end{cases}$ 

Where it is assumed that Xo is such that admissible controls can transfer the state to gevo (see Problem 5-24).

(c) For those states for which an optimal control exists when any the time-optimal solutions are the same for axo and for axo.

For those states for which an optimal control exists when aro, the fuel-optimal solution for aro is identical to the time optimal solution for aro and for aco. This fuel-optimal solution is quite different than the results obtained for the fuel-optimal problem when a < 0 (see Examples 5.5-2, 5.5-3, and 5.5-4). The difference is caused by the fact that with aro the system is unstable and moves away from the origin when no control is applied; thus, coasting increases the fuel required.

5-29 (a)  $\mathcal{H} = |u(t)| + p_1(t) x_2(t) + p_2(t) x_1(t) + p_2(t) x_2(t) u(t)$ .

$$\dot{\rho}_{i}^{*}(t) = -\frac{\partial \mathcal{E}}{\partial x_{i}}(x, t) = -\rho_{2}^{*}(t)$$

 $\dot{p}_{2}^{*}(t) = -\frac{\partial \mathcal{X}}{\partial x_{2}}(*,t) = -p_{1}^{*}(t) - p_{2}^{*}(t) u^{*}(t).$ 

(b) The form of the state equations is as assumed in Eq. (5.5-5) of the text; hence, the optimal control is given by Eq. (5.5-14), that is,

 $U^{*}(t) = \begin{cases} 1, & p_{2}^{*}(t) \times_{2}^{*}(t) < -1 \\ 0, & -1 < p_{2}^{*}(t) \times_{2}^{*}(t) < 1 \end{cases}$ Undetermined,  $p_z^*(t) \times_z^*(t)$   $p_z^*(t) \times_z^*(t) = \pm 1.$ 

 $\mathcal{H} = \lambda + \sum_{i=1}^{m} r_{i,i} u_i^{2}(t) + \mathcal{P}^{T}(t) \mathcal{Q}(\mathcal{Z}(t), t)$ + pt(t) B(x(t),t) &(t).

PT(t) B(xlt),t) can be written [2 (t) b, (x(t) t) 2 (x(t) t) ... 2 (t) b, (x(t)) where be is the ith column of B. Then the terms in X which involve

y are  $\sum_{t=0}^{\infty} \left[ r_{i,t} u_i^{2}(t) + p^{T}(t) k_i(x(t),t) u_i(t) \right].$ 

5-30 (cont.)

If the controls are not constrained the extremal controls are found from 
$$0 = \frac{\partial \mathcal{L}}{\partial u_i}(x,t) = 2\pi_i u_i^*(t) + 2^*T(t) b_i(x^*(t),t)$$

or,

 $u_i^*(t) = -\frac{1}{2\pi_{ii}} 2^*T(t) b_i(x^*(t),t)$ 
 $i = 1,2,...,m$ .

If the controls are constrained by  $|u_i(t)| \leq 1$ ,  $i = 1,2,...,m$ , then,

 $|u_i^*(t)| \leq 1$ ,  $i = 1,2,...,m$ ,

 $|u_i^*(t)| \leq 1$ ,  $|u_i^*(t)| b_i(x^*(t),t)$ ,  $|x^*T(t)| b_i(x^*(t),t)$ 

5-3/
(a) 
$$t = 1 + p_1(t) x_2(t) - p_2(t) g - \frac{k p_2(t)}{x_3(t)} u(t) + p_2(t) u(t)$$

$$p_1^*(t) = -\frac{\partial \mathcal{L}}{\partial x_1}(x, t) = 0$$

$$p_2^*(t) = -\frac{\partial \mathcal{L}}{\partial x_2}(x, t) = -p_1^*(t)$$

(-1, 1≤ \frac{1}{200} \pop^\*T(t) \bi.

$$\dot{\rho}_{3}^{*}(t) = -\frac{\partial \mathcal{H}}{\partial x_{3}}(*,t) = \frac{-k \rho_{2}^{*}(t)}{x_{3}^{*2}(t)} u^{*}(t).$$

The boundary conditions are  $x_{i}^{*}(t_{f}) = 0$ ,  $x_{i}^{*}(t_{f}) = 0$ ,  $p_{i}^{*}(t_{f}) = 0$ ,  $p_{i}^{*}(t_{f}) = 0$ .

(b) 
$$\mathcal{H} = |u(t)| + p_1(t) \times_2(t) - p_2(t)g - \frac{kp_2(t)}{x_3(t)}u(t) + p_3(t)u(t)$$

The costate equations and boundary conditions are as given in part (a). The control which minimizes the is given by

$$u^{*}(t) = \begin{cases} -M, & 1 < p_{3}^{*}(t) - \frac{k p_{2}^{*}(t)}{x_{3}^{*}(t)} \\ 0, & p_{3}^{*}(t) - \frac{k p_{2}^{*}(t)}{x_{3}^{*}(t)} < 1 \\ & \text{undetermined, } p_{3}^{*}(t) - \frac{k p_{2}^{*}(t)}{x_{3}^{*}(t)} = 1. \end{cases}$$

An alternative formulation is to let J = - x3(tq); doing this we have

 $\mathcal{X} = p_1(t) x_2(t) - p_2(t) g - \frac{k p_2(t)}{x_3(t)} u(t) + p_3(t) u(t).$ 

The costate equations are unchanged; however, the expression for the optimal control is as given in Eq. (5.4-25) of the text. The boundary conditions are

$$x_{1}^{*}(t_{f}) = 0$$
,  $x_{2}^{*}(t_{f}) = 0$ ,  $p_{3}^{*}(t_{f}) = -1$ ,  $X(*,t_{f}) = 0$ .

(c) 
$$\frac{d}{dt} \left[ \dot{x}(t) \right] = -g - k \frac{d}{dt} \left[ ln \left( m(t) \right) \right]$$
.

Integrating both sides from 0 to t gives  $\dot{x}(t) = \dot{x}(0) - gt - k \ln(m(t)/m(0))$ .

Letting t=tf, and solving for m(tf) gives

$$5-31 (cont.)$$
  
 $m(t_f) = m(0) \in \frac{1}{k} (\dot{x}(0) - gt_f)$   
 $= m(0) \in \dot{x}(0)/k \in -gt_f/k$ 

 $m(t_F) = c_1 e^{-gt_F/k}. \qquad (I)$ 

In obtaining this result we have used the fact that  $\dot{x}(t_f)=0$ .

Eq. (I) clearly shows that the larger to is, the smaller the final mass is. This implies that fuel expenditure is a monotone increasing function of the final time; hence, the minimum-time and minimum-fuel solutions are identical.

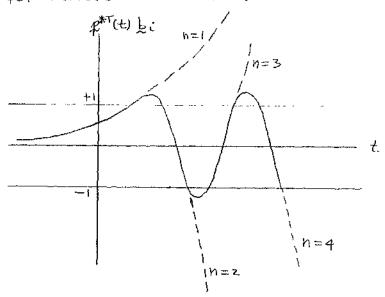

*5-32* 

For the minimum-time case there are at most (n-1) switchings; hence, the functions

P\*T(t) bi, i=12,..., m

have at most (n-1) zeros. In the minimum - fuel case we are interested in how many times

passes through the values ±1. Since passes through the values ±1. Since  $p^{*T}(t)$  by has only (n-1) zeros, it is seen that  $p^{*T}(t)$  by also has at most (n-1) maxima and minima (see sketch below). The dashed curves show

It is not difficult to convince oneself that the curve shown for nell yields the maximum possible number of switchings (1). Similarly, the other possibilities shown represent situations in which the maximum number of crossings of the £1 points occur. Counting the maximum number of switchings for the values of n shown leads to (2n-1) as the upper bound on the number of control switchings. It should also be clear that this should also be clear that this upper bound also applies for larger values of n.

140

(a) 
$$\gamma_{e,=} = \lambda + \sum_{i=1}^{m} |u_i(t)| + p^{T}(t) \left[ \frac{\alpha(xt)}{\alpha(xt)} + \beta(x(t),t) \right] + \beta(x(t),t)$$

$$\begin{aligned} \mathcal{H}_z &= 1 + \rho^T(t) \left[ \underline{\alpha}(\underline{x}(t),t) + \underline{\beta}(\underline{x}(t),t) \, \underline{u}(t) \right] \\ \mathcal{H}_3 &= \sum_{i=1}^{m} |u_i(t)| + \rho^T(t) \left[ \underline{\alpha}(\underline{x}(t),t) + \underline{\beta}(\underline{x}(t),t) \, \underline{u}(t) \right]. \end{aligned}$$

(b) In all three cases the costate equations are given by 
$$\dot{P}_{i}^{*}(t) = -\frac{\partial}{\partial x_{i}} \left[ P^{*T}(t) \left\{ 2(x_{i}^{*}(t),t) + B(x_{i}^{*}(t),t) \right\} \right].$$

$$5-34$$
(a)  $X=\lambda+|u(t)|+p_1(t)X_2(t)-ap_2(t)X_2(t)+p_2(t)U(t)$ 

$$\dot{p}_{1}^{*}(t) = -\frac{\partial + c}{\partial x_{1}}(*,t) = 0 \Rightarrow p_{1}^{*}(t) = c_{1}$$

$$\dot{p}_{2}^{*}(t) = -\frac{\partial + c}{\partial x_{2}}(*,t) = -p_{1}^{*}(t) + \alpha p_{2}^{*}(t)$$

$$= -c_{1} + \alpha p_{2}^{*}(t)$$

$$U^{*}(t) = \begin{cases} -1, & \rho_{2}^{*}(t) > 1 \\ 0, & -1 < \rho_{2}^{*}(t) < 1 \\ +1, & \rho_{2}^{*}(t) < -1 \end{cases}$$

+1, 
$$p_2^*(t) < -1$$
  
undetermined,  $p_2^*(t) = \pm 1$ .

(b) The solution of the Second costate equation is of the form

$$p_2^*(t) = c_2 + c_3 e^{at}$$
. (I)

By sketching the possible forms for pt(t) it is found that the candidates for optimal controls have the forms

 $U = \{-1\}, \{0\}, \{+1\}, \{0,-1\}, \{0,+1\}, \{-1,0$ 

(c) Since to is free and X does not depend explicitly on t, X is identically zero on an extremal trajectory. We also know that if p\*(t) = +1, then u\*(t), although undetermined, is non-positive (see Eq. (5.5-14) of the text). It also can be shown that in (I) the expression for p\*(t) the value for c2 is c1/a. Using these relationships and assuming that p\*(t) = 1 for a finite time interval, we have

) = ) + | (t) | + c1 xt(t) - axt(t) + (x\*(t)).

But, since  $p_2^*(t) = 1$  for a finite time interval,  $c_3 = 0$ ,  $c_2 = c_1/a = 1 \Rightarrow c_1 = a_2$ ; thus,

X= \+ | u\*(t) | + u\*(t).

But we know that for  $p_2^*(t)=1$ ,  $u^*(t) \le 0$ ; therefore  $\{u^*(t)\}=-u^*(t)$  and  $\mathcal{X}=\lambda\neq 0$ , a contradiction.

It can be shown in a similar manner that px\*(t) cannot be equal to -1 for a 'non-zero time interval; thus, singular intervals cannot exist. (d) The procedure here is essentially the same as that used in solving Example 5.5-5 in the text. First, consider only those trajectories which terminate with an interval of u=-1, that is, u= {-1}, {0,-1}, {1,0,-1} The results obtained in Example 5.4-5 of the text can be used to give

 $\chi_1(t) = \frac{1}{a^2} \ln \left( 1 + a \chi_2(t) \right) - \frac{1}{a} \chi_2(t)$ 

as the equation for the u=-1 trajectory which passes through the origin. Eq. (I) also describes the switching curve where the control changes from 0 to -1. Next, we need to determine the curve where u switches from +1 to O. First, we solve the state equations using u=0 to obtain

 $\chi_{i}(t_{z}) = \chi_{i}(t_{i}) + \frac{1}{4} \left[ i - \epsilon^{-a(t_{z}-t_{i})} \right] \chi_{z}(t_{i}) \left( \mathbb{Z} \right)$  $x_2(t_2) = x_2(t_1) \in -a(t_2 - t_1)$ .

In the expression (I) for  $p_2^*(t)$  it can be shown that  $c_2 = c_1/a_2$ 

143

therefore, we have

$$p_2^*(t_1) = \frac{c_1}{a} + c_3 e^{at_1} = -1$$
 (\pi)

$$p_2^*(t_2) = \frac{c_1}{a} + c_3 e^{at_2} = +1;$$
 (III)

to refers to the time when us switches from the value +1 to 0, and to is the time when us switches from o to -1. Since to is free and He does not depend on the explicitly, we know that He must be zero on an extremal trajectory. Using this knowledge, Eqs. (X) and (VI), and the knowledge that u\*(ti) ≥0 and u\*(to) ≤0, we obtain

$$\lambda + c_1 \chi_2(t_1) + a \chi_2(t_1) = 0$$
 (VII)

$$\lambda + c_1 \times_2 (t_2) - a \times_z (t_2) = 0$$
. (VIII)

Our objective is to solve for  $x_1(t_1)$  in terms of  $x_2(t_1)$ . We begin by solving (II) and (II) for  $(t_2-t_1)$  with the result

$$t_2-t_1=\frac{1}{a}\ln\left(\frac{c_1-a}{c_1+a}\right).$$

To eliminate ci, we solve (VII) to obtain

$$c_{i} = -\frac{\lambda - \alpha x_{2}(t_{i})}{x_{2}(t_{i})}.$$

5-34 (cont.)

Eliminating c, gives  $(t_2-t_1)=\frac{1}{2}\ln\left(\frac{\lambda+2a\times_2(t_1)}{\lambda}\right)$ 

which when substituted in (III) and (III) gives

 $\chi_{1}(t_{2}) = \chi_{1}(t_{1}) + \frac{\chi_{2}(t_{1})}{a} - \frac{\lambda \chi_{2}(t_{1})}{a[\lambda + za\chi_{2}(t_{1})]}$ 

 $x_2(t_2) = \frac{\lambda x_2(t_1)}{\lambda + 2a x_2(t_1)}$ .

Using (II) we obtain then

 $\chi_{1}(\pm_{2}) = \frac{1}{a^{2}} \ln \left(1 + \frac{a\lambda \chi_{2}(\pm_{1})}{\lambda + 2a\chi_{2}(\pm_{1})}\right) - \frac{1}{a} \frac{\lambda \chi_{2}(\pm_{1})}{\lambda + 2a\chi_{2}(\pm_{1})}$ 

 $= \chi_{1}(t_{1}) + \frac{\chi_{2}(t_{1})}{\alpha} \left[1 - \frac{\lambda}{\lambda + 2\alpha\chi_{2}(t_{1})}\right]$ 

 $x_{1}(t_{1}) = -\frac{1}{a} x_{2}(t_{1}) + \frac{1}{a^{2}} ln \left(1 + \frac{a\lambda x_{2}(t_{1})}{\lambda + 2a x_{2}(t_{1})}\right).$ 

This equation, which applies for x200, is the sought after result

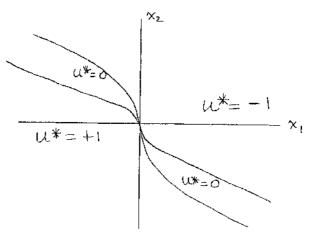

is the sought after result, Using similar reasoning, it can be shown that U switches from

-1 to 0 where

 $x_1(tz') = -\frac{1}{\alpha} x_2(tz') - \frac{1}{\alpha^2} \ln (1 - \alpha x_2(tz'))$ and that switching from 0 to +1 occurs where

$$x_{1}(t_{1}') = -\frac{x_{2}(t_{1}')}{a} - \frac{1}{a^{2}} \ln \left(1 - \frac{a\lambda x_{2}(t_{1}')}{\lambda - 2ax_{2}(t_{1}')}\right).$$

These last two switching curves apply for x2 < 0. The switching curves and the optimal control law are shown below.

5-35

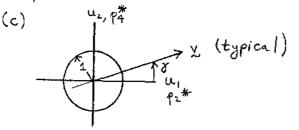

(a) 
$$t = 1 + p_1(t) \times_2(t) - dp_2(t) \times_2(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$$
 $t = 1 + p_1(t) \times_2(t) - dp_2(t) \times_2(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) - dp_4(t) \times_4(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) - dp_4(t) \times_4(t) \left[ x_2^2(t) + x_4^2(t) \right]$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) \times_4(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) \times_4(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) \times_4(t) \times_4(t) \times_4(t) \left[ x_2^2(t) + x_4^2(t) \right]^{1/2}$ 
 $t = 1 + p_1(t) \times_2(t) \times_4(t) \times_4(t)$ 

$$p_{3}^{*}(t) = -\frac{\partial \mathcal{H}}{\partial x_{5}}(*,t) = 0$$

$$p_{4}^{*}(t) = -\frac{\partial \mathcal{H}}{\partial x_{4}}(*,t) = -p_{3}^{*}(t) + d p_{4}^{*}(t) \left\{ \frac{x_{5}^{*}(t) + 2x_{5}^{*}(t)}{[p_{5}^{*}(t)]^{1/2}} \right\}$$

$$+ \frac{d p_{5}^{*}(t) x_{5}^{*}(t) x_{5}^{*}(t)}{[p_{5}^{*}(t)]^{1/2}}.$$

(b) 
$$x^*(t_f) = e_1, p_2^*(t_f) = 0, x_3^*(t_f) = e_3$$
  
 $p_4^*(t_f) = 0, \mathcal{K}(*, t_f) = 0.$ 

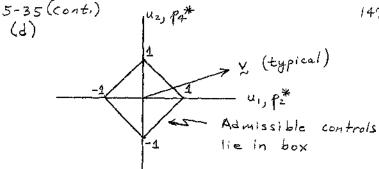

Let X = [px\*(t) px\*(t)] ; we seek the admissible u\* which minimizes

 $y^T u$ .

Assuming  $X \neq 0$ , the admissible control that minimizes  $X^T u$  has the largest possible amplitude, i.e. u,2(+)+u\*(+)=1, and is directed oppositely to X; therefore,

 $u^*(t) = -\cos \delta(t)$ ,  $u^*(t) = -\sin \delta(t)$ ,  $\lambda(t) = \tan^{-1} \left[ \frac{p_4^*(t)}{p_*(t)} \right].$ 

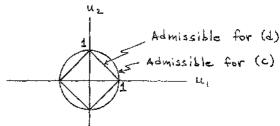

(4)

By inspection it is seen that (except when the angle of X is 45°, 135°, 225°, and 315°) the maximum projection of a vector w onto x occurs when w lies at one of the vertices , the y that minimizes XT lies at the opposite vertex. The minimizing control

以\*(t)=[-1 可T, |作(t)/p\*(t)|<1, p\*(t)>0 [1 o] , | p\*(t)/p\*(t) < 1, p\*(t) < 0 [0 -I], 194(t)/12(t) >1, 12(t)>0 [0 ]T, |pt(t)/pt(t)/>1, pt(t)<0.

(e) Part (c) controls must be at least as effective as Part (d) controls; as seen in the sketch below, every admissible control for part (d) is also admissible for part (c) -- the reverse is not true, however. Thus,  $J_{c} \leq J_{d}$ .

5-36 We will assume, as in Example 5.5-5, that  $\chi(t_2)=0$ .

(a) 
$$\mathcal{H} = |u(t)| + p_1(t)\chi_2(t) + p_2(t) |u(t)|$$
  
 $p_1^*(t) = -\frac{\partial \mathcal{H}}{\partial \chi_1}(*_1t) = 0 \Rightarrow p_1^*(t) = c_1$   
 $p_2^*(t) = -\frac{\partial \mathcal{H}}{\partial \chi_2}(*_1t) = -p_1^*(t) \Rightarrow p_2^*(t) = -c_1t + c_2.$ 

(b) If there are no singular intervals,

$$u^{*}(t) = \begin{cases} -1, & p_{2}^{*}(t) > 1 \\ 0, & |p_{2}^{*}(t)| < 1 \\ +1, & p_{2}^{*}(t) < -1. \end{cases}$$

To show the existence of non-unique optimal controls we first find a lower bound on the fuel required to transfer the system to the origin. From the second state equation

5-36(cont.)  $x_z(t) = x_{zo} + \int_0^t u(t) dt$ , (±)

but, we have assumed that  $x_2(t_f)=0$ , hence,  $|x_{20}|=|\int_{-\infty}^{t} u(t) dt| \leq \int_{-\infty}^{\infty} |u(t)| dt$ .

Thus, if we can construct a control signal which satisfies

$$|x_{z_0}| = \int_{a}^{t_f} |u(t)| dt, \qquad (\pm)$$

then this control signal is fuel optimal. To determine such a control we notice in (I) that if ult) does not change sign, then (II) will be satisfied. Note that to is not specified.

Actually, it is not difficult to generate many optimal controls. For example, if we assume that

$$u(t) = \begin{cases} 0 < M_1, & t \in [0, t_1] \\ 0, & t \in (t_1, t_2) \\ 0 < M_2, & t \in [t_2, t_f] \end{cases}$$

it can be shown that

$$x_1 t_p = 0 = x_{10} - \frac{1}{2} M_1 t_1^2 + x_{20} t_1 + M_1 t_1 t_2 - M_2 t_2 t_1 + \frac{1}{2} M_2 t_2^2 + \frac{1}{2} M_2 t_2^2$$
 (III)

$$\chi_2(t_f)=0=\chi_{20}+M_1t_1+M_2t_4-M_2t_2$$
. (IV)

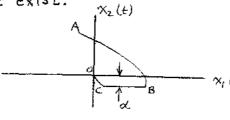

5-36 (cont.)

Suppose  $X_0 = [A - i]^T$ . If we let  $M_1 = M_2 = .5$  and  $t_1 = I$ , (III) and (IV) can be solved for  $t_2 = 7$  and  $t_5 = 8$ . Similarly, if  $M_1 = M_2 = .25$ ,  $t_1 = 2$ , solving (III) and (IV) gives  $t_2 = 6$ ,  $t_5 = 8$ . Both of these control signals (and many more) require the minimum fuel possible, and hence are optimal.

(c) Consider the trajectory shown below; the initial segment corresponds to u(t) = -1. The segment B-c results from u(t) = 0, and c-o results from u(t) = 1. It is easily verified that the fuel required is equal to

1x201+2x.

In the limit as d >0, the required fuel approaches the lower bound on fuel expenditure; however, as d >0, tf > 00. Thus, the fuel required can be arbitrarily close to, but never attain, the lower bound. This means that a minimum-fuel control does not exist.

5-36 (cont.)

(d) Singular intervals can exist if  $p_z^*(t) = \pm 1$  for a finite time interval. This occurs if  $c_1 = 0$ ,  $c_2 = \pm 1$ , and, if so, the condition that  $t \in (*,t) = 0$  is satisfied. This indicates that singular intervals can exist; the controls generated in part (b) are in fact singular and optimal.

5-38

(a)  $\chi = \frac{1}{2} \chi_1^2(t) + p_1(t) \chi_2(t) + p_1(t) u(t) - p_2(t) u(t)$   $\dot{p}_1^*(t) = -\frac{\partial \chi}{\partial \chi_1}(*,t) = -\chi_1^*(t)$ (I)  $\dot{p}_2^*(t) = -\frac{\partial \chi}{\partial \chi_2}(*,t) = -p^*(t)$ .

(II)

The boundary conditions are  $\chi(t_{\rm f})=Q$ .

(4) Minimizing ) with respect to u gives

$$u^{*}(t) = \begin{cases} -1, & 0 < p_{1}^{*}(t) - p_{2}^{*}(t) \\ +1, & p_{1}^{*}(t) - p_{2}^{*}(t) < 0 \end{cases}$$

$$\text{Undetermined, } p_{1}^{*}(t) - p_{2}^{*}(t) = 0.$$

A singular interval can exist if  $p_i^*(t) - p_z^*(t) = 0$ , for  $t \in [t_i, t_i]$ . (III) Combined with the necessary condition that f(\*,t) = 0 for f(\*,t) = 0 for f(\*,t) = 0 implies that

 $\frac{1}{2} \times_{i}^{*2}(t) + p_{i}^{*}(t) \times_{i}^{*}(t) = 0$ , for te[t, t\_i].(IV) Differentiating (IV) and setting the result equal to zero gives

 $X_{\star}^{*}(t) \dot{X}_{\star}^{*}(t) + p_{\star}^{*}(t) \dot{X}_{\star}^{*}(t) + p_{\star}^{*}(t) \dot{X}_{\star}^{*}(t) = 0$ . (I) Substituting the expression  $p_{\star}^{*}(t) = -x_{\star}^{*}(t) p_{\star}^{*}(t)$  from Eq. (IV) and the right sides of the state and costate equations for  $\dot{X}_{\star}^{*}(t)$ ,  $\dot{X}_{\star}^{*}(t)$  and  $\dot{p}_{\star}^{*}(t)$  into Eq. (V), and rearranging yields

2 x1\*(t) x\*(t) + x\*2(t) = 0 , te[to, t]

or

Hence, the candidates are  $\chi_{*}^{*}(t)=0$ ,  $\chi_{*}^{*}(t)=-2\chi_{*}^{*}(t)$ .

From the state equations  $\chi^*(t)=0 \Rightarrow \dot{\chi}^*(t)=0 \Rightarrow u^*(t)=-\chi^*(t)$ , but this trajectory always moves away from the desired final state (the origin) along the vertical axis, hence it cannot be optimal.

on the other singular segment,  $\chi_{*}(t) = -2\chi_{z}^{*}(t)$ , the state equations indicate that

 $x_1^*(t) = -2x_2^*(t) \implies x_1^*(t) = -2x_2^*(t) = 2(x_1^*(t)) = (x_1^*(t) + x_2^*(t))$ 

Thus,

 $u^{*}(t) = x_{2}^{*}(t).$ 

whether or not this singular trajectory segment is a part of any optimal trajectories must be determined by further investigation.

5-40

$$\mathcal{H} = 1 + p_1(t) \times_2(t) - g p_2(t) - \frac{k p_2(t)}{x_3(t)} u(t) + p_3(t) u(t) 
\dot{p}_1^*(t) = -\frac{\partial k}{\partial x_1}(*,t) = 0 \Rightarrow p_1^*(t) = c_1 
\dot{p}_2^*(t) = -\frac{\partial k}{\partial x_2}(*,t) = -p_1^*(t) \Rightarrow p_2^*(t) = -c_1t + c_2 
\dot{p}_3^*(t) = -\frac{\partial k}{\partial x_3}(*,t) = -k p_2^*(t) u^*(t) / x_3^{*2}(t) .$$

A singular interval exists if

$$p_{x_{2}}^{*}(t) - \frac{kp_{2}^{*}(t)}{x_{2}^{*}(t)} = 0$$
,  $t \in [t_{1}, t_{2}]$ . (1)

Recall that k>0,  $X_3^*(t)>0$ . Since  $t_f$  is free and t does not appear explicitly in H, H(\*,t)=0,  $t\in [t_0,t_f]$ . Thus, if (T) is satisfied

1+  $p_i^*(t) \times_2^*(t) - g p_2^*(t) = 0$ ,  $t \in [t_i, t_2]$  (II) Since (II) holds for a finite time interval, the derivative with respect to time of the left side of (II) must also be zero for te [t\_i, t\_2], hence  $p_i^*(t) \times_2^*(t) + p_i^*(t) \times_2^*(t) - g p_2^*(t) = 0$ ,  $t \in [t_i, t_2]$ . Substituting  $p_i^*(t) = 0$ ,  $p_i^*(t) = -c_i$ , and  $x_i^*(t) = -g - ku^*(t)/x_i^*(t)$  gives  $c_i[-g - \frac{ku^*(t)}{x_i^*(t)}] + gc_i = 0 \implies c_i ku^*(t) = 0$ 

because xx\*(t) > 0. There are then two subcases to consider.

(i) Suppose  $c_1=0$ , then (II) implies that  $p_*^*(t)=1/g$ . Since  $x_*^*(t_f)$  is free,  $p_*^*(t)=0$ , using the fact that  $u_*(t) \le 0$  and  $p_*^*(t)=1/g$  in the third costate  $p_*^*(t)=1/g$  in the third costate equation gives  $p_*^*(t) \ge 0$ ,  $t \in [t_0, t_f]$ . This implies that  $p_*^*(t) \le 0$  for  $t \in [t_0, t_f]$ . Looking at  $p_*^*(t) - [kp_*^*(t)/x_*^*(t)]$  we see that since  $p_*^*(t) \le 0$ ,  $p_*^*(t) > 0$ ,  $x_*^*(t) > 0$ ,

-kp\*(t)/x\*(t) <0 and hence

p\*(t) - kp\*(t) <0; a contradiction

which implies that a singular interval

cannot exist.

(ii) Suppose  $u*(t)=0 \Rightarrow p^*(t)=0$  and  $x^*_3(t)=0$  which in turn implies that  $p^*_3(t)=C_3$  and  $x^*_3(t)=C_4$  for  $t\in [t_1,t_2]$ . Hence, (t) can hold only if  $p^*_2(t)=a$  constant= $C_2$ , but this implies that  $p^*_3(t)=C_1=0$  for  $t\in [t_1,t_2]$  and we have already shown that a singular interval cannot exist if  $C_1=0$ .

5-40 (cont.)

Our conclusion is then that a singular interval cannot exist,

5-41

(a)  $\mathcal{H} = \lambda + |u(t)| + p_1(t) \times_2(t) + p_2(t) \cdot u(t)$ 

A singular interval exists if ptt=±1.

The costate equations are

 $\dot{p},*(t) = -\frac{\partial \mathcal{X}}{\partial x}(*,t) = 0 \implies p*(t) = 0,$ 

 $p_2^*(t) = -\frac{\partial \mathcal{L}}{\partial x_2}(x,t) = -p^*(t) \Rightarrow p_2^*(t) = -c_1 t + c_2$ .

If px(t) = ±1, to [t,t], then c=0, cz=±1 => pi\*(t)=0, te[to,tf]. But this implies that  $\mathcal{K}(*,t) = \lambda > 0$  which contradicts the necessary condition that X(x,t)=0;

therefore, a singular interval cannot exist.

(b)  $\mathcal{L} = \lambda + |u(t)| + \mathcal{L}^{\mathsf{T}}(t) \wedge \mathcal{L}(t) + \mathcal{L}^{\mathsf{T}}(t) \wedge u(t)$ 

If f\* (t) b= ±1, a singular interval exists. If p\*Th = ±1 ⇒ p\*T(t) A = 2

(as in part (a) of this problem) then we have  $\mathcal{H}(*,t) = \lambda > 0$  which contradicts

the necessary condition that ) (\*x,t)=0,

in which case a singular interval

eannot exist. It does not seem possible to show that in general p\*(t) b = ±1

=> A\*T(+)A = Q. We can, however, show

as in Section 5.6 that a singular interval can exist only if either A or [b|Ab|...|An-1b], or both, are singular. Notice that this is not a sufficient condition for the existence of a singular interval — in part (a) A is singular, but a singular interval does not exist.

## CHAPTER 6

6-1

(a) The desired value of p(tf) is d. Noting that p(tx) is a function of p(to) we can write

$$\mathcal{R}(f) = f(\mathcal{R}(f)).$$

Expanding in a Taylor series and retaining terms of up to first order gives  $p^{(i+1)}(t_{\epsilon}) = p^{(i)}(t_{\epsilon}) + \left[\frac{\partial f}{\partial z}(p^{(i)}(t_{0}))\right] \left[p^{(i+1)}(t_{0}) - p^{(i)}(t_{0})\right].$ 

The matrix of/of is the same as the (#) matrix denoted by Pp(p(i)(to),tx). To save writing, we will shorten this to P(1).

Since we desire to make p(+)=d, we set p(i+1)(tf) = d in (I) and solve for R(i+1)(to) with the result

$$p^{(i+1)}(t_0) = p^{(i)}(t_0) - [p^{(i)}]^{-1} [p^{(i)}(t_0) - d].$$

(b) In this case, the desired value of p(4) is at x(4), so we set p(4) (4) = 2# x(1+1)(4). For the dependence of X(ta) on R(to) we have the equation analogous to (=),

Replacing  $p^{(i+1)}(t_F)$  in (I) by 2H  $\chi^{(i+1)}(t_F)$  and using the right side of (II) gives

6-1 (conti) 2世 X(1)(七) +2世[ Px(1)] [宋(1+1)(七)-宋(1)(七)] = & (i) (ta) + [ ] [ & (i+1) (to) - & (i) (to) ]. Solving for pritil (to) gives  $\mathcal{P}^{(i+1)}(\mathbf{b}) = \mathcal{Z}^{(i)}(\mathbf{b}) + \left[ 2 \sharp \mathcal{Z}_{x}^{(i)} - \mathcal{P}_{p}^{(i)} \right]^{-1} \left[ \mathcal{P}^{(i)}(\mathbf{b}) - 2 \sharp \mathcal{Z}^{(i)}(\mathbf{b}) \right].$ (c) Here the desired final costate is on (x(bx)), so we set

 $\mathcal{L}^{(i+1)}(t_{\mathcal{L}}) = \frac{\partial h}{\partial x} \left( x^{(i+1)}(t_{\mathcal{L}}) \right).$ 

In general this will be a nonlinear relationship in  $X^{(i+1)}(t_f)$ , Although we could substitute the right side of (II) for X(i+1)(ts), we will first simplify matters by linearizing on (x(i+1)(ts)) about the point X(i)(tx); doing this gives

 $\mathcal{R}^{(i+1)}(t_{+}) = \frac{\partial h}{\partial x} \left( \chi^{(i)}(t_{+}) \right) + \left[ \frac{\partial^{2} h}{\partial x^{2}} \left( \chi^{(i)}(t_{+}) \right) \right] \left[ \chi^{(i+1)}(t_{+}) - \chi^{(i)}(t_{+}) \right].$ Substituting the right side of (II) for  $\chi^{(i+1)}(t_f)$  and using (II) yields

 $\mathcal{L}_{(i)}(\mathbf{r}^2) + \mathcal{L}_{(i)} \left[ \mathcal{L}_{(i+1)}(\mathbf{r}^0) - \mathcal{L}_{(i)}(\mathbf{r}^0) \right] = \frac{2^{N}}{9^{N}} \left( \mathcal{L}_{(i)}(\mathbf{r}^2) \right)$ 

 $+ \left\lceil \frac{\partial^2 h}{\partial x^2} \left( \chi^{(i)}(t_f) \right) \right\rceil P_{x}^{(i)} \left[ \chi^{(i+1)}(t_0) - \chi^{(i)}(t_0) \right].$ 

Solving for p((+1) (to) we obtain  $\mathcal{P}^{(i+i)}(b) = \mathcal{P}^{(i)}(b) + \left[ \left[ \frac{\partial^2 h}{\partial x^2} (x^{(i)}(b)) \right] \mathcal{P}^{(i)}_{x} - \mathcal{P}^{(i)}_{y} \right]^{-1} \left[ \mathcal{P}^{(i)}(b) - \frac{\partial h}{\partial x} (x^{(i)}(b)) \right]$  6-1 (cont.) (d) To obtain the result of part (a) substitute  $\frac{\partial h}{\partial x} = d$ ,  $\frac{\partial^2 h}{\partial x^2} = Q$  in (TV).

To obtain the result given in part (b) substitute  $\frac{\partial h}{\partial x} = 2 \pm x$ ,  $\frac{\partial^2 h}{\partial x^2} = 2 \pm in$  (IV).

To obtain Eq. (6.3-18) of the text set  $\frac{\partial h}{\partial x} = 2$ ,  $\frac{\partial^2 h}{\partial x^2} = 2$  in (III).

For a regulator problem with H=Q, p(tf) = 2 and the reduced DiE, are

发(t) = 及(t)炎(t) + 见(t) 2(t) · (t) = 点(t) &(t) + &(t) 和(t),  $(\pm)$ 

where D(t) ≜ -B(t) R-1(t) B+(t) E(+) = - 2(+)

€(t) = - A<sup>T(t)</sup>.

The solution of (I) has the form

 $\begin{bmatrix} \chi(t) \\ \overline{\chi}(t) \end{bmatrix} = \begin{bmatrix} \underline{\mathcal{L}}_{11}(t) & \underline{\mathcal{L}}_{12}(t) \\ \overline{\mathcal{L}}_{11}(t) & \underline{\mathcal{L}}_{22}(t) \end{bmatrix} \begin{bmatrix} \chi(t_0) \\ \overline{\chi}(t_0) \\ \overline{\chi}(t_0) \end{bmatrix}$ 

hence p(4) = £2, (4) x(6)+£22(4) \$(6),

and  $P_{\downarrow\downarrow} \triangleq \frac{\partial p(t)}{\partial a(t)} = \mathcal{L}_{22}(t_{\downarrow}).$  Substituting (II) into Eq. (6.3-18) of the text gives

 $p^{(1)}(t_0) = -[f_{22}(t_f)]^{-1}f_{21}(t_f) \times (t_0).$ 

Using (III) in (6.3-18) to find p(2)(6)

 $g^{(2)}(t_0) = - \left[ \mathcal{L}_{22}(t_0) \right]^{-1} \mathcal{L}_{21}(t_1) \propto (t_0),$ 

but this equals p<sup>(1)</sup>(to), hence the procedure converges in one iteration regardless of the choice of p<sup>(0)</sup>(to).

Noting that x(tx) is a fcn. of p(to) we write

 $\chi(t_{\epsilon}) = f(\chi(t_{0})).$ 

Expanding in a Taylor series about  $\chi^{(i)}(t_f)$  and retaining terms of up to first order, we have

 $X_{(i+i)}(f^2) = X_{(i)}(f^2) + \left[\frac{2\xi}{3\xi}(\xi_{(i)}(f^0))\right][\xi_{(i+i)}(f^0) - \xi_{i}(f^0)]$ 

 $\triangleq \chi^{(i)}(t_{x}) + \left[P_{x}^{(i)}\right] \left[\chi^{(i+1)}(t_{0}) - \chi^{(i)}(t_{0})\right].$ 

Since the desired final state value is  $x_f$ , we set  $x^{(i+1)}(t_f) = x_f$  and solve for  $x^{(i+1)}(t_0)$  to obtain

 $\mathcal{R}^{(i+1)}(t_0) = \mathcal{R}^{(i)}(t_0) - \left[ \mathcal{R}^{(i)}_{x} \right]^{-1} \left[ \chi^{(i)}(t_{\overline{x}}) - \chi_{\overline{x}} \right].$ 

6-4 Suppose that in the performance measure

h=0, and that

6-4 (conti) 161 x,(4)= x1, , ", xr(4) = xr, are specified. Then front (tx) = 0, ..., pn (tx) = 0. Noting that the state and costate values depend on q(to) we write (also using a Taylor series)  $\chi_{i}(\mathsf{t}_{\mathcal{G}}) = f_{i}(\mathfrak{P}(\mathsf{to})) \implies \chi_{i}^{(i+1)}(\mathsf{t}_{\mathcal{G}}) = \chi_{i}^{(i)}(\mathsf{t}_{\mathcal{G}}) + \left[\frac{\partial f_{i}}{\partial f_{i}}(\mathfrak{P}(\mathsf{to}))\right] \left[g^{(i+1)}(\mathsf{to})\right]$ Hereaster, we omit p(1)(to) in 25(p(1)(to)/2p)  $\chi_{z}(t_{\mathcal{L}}) = f_{z}(\mathcal{L}(t_{\mathcal{L}})) \Rightarrow \chi_{z}^{(i,t_{\mathcal{L}})}(t_{\mathcal{L}}) = \chi_{z}^{(i)}(t_{\mathcal{L}}) + \left[\frac{\partial f_{z}}{\partial \rho}\right]^{T} \left[\rho^{(i+1)}(t_{\mathcal{L}}) - \rho^{(i,i)}(t_{\mathcal{L}})\right]$ 水(は)= fr(を(も)) > x(い)(は)= x(い(は)+[ofr] [p(い)(は)-p(い(は) (中) = fre((を)) = pre((女) + (女) + (女) + (女) - p(i) (も) - p(i) (も)

Prity = fn (p(b)) => pn (tx) = pn(i)(tx) + [3tn] [2(i+1)(ta) - p(i)(ta)].

Let Z(1) △ [x(1)(年), ..., x(1)(年), +(1)(年), ..., +(1)(年)],

then

₹ = [x1 + 1 ... x + 0 , ... 0] = desired

From the series expansions written in matrix form we have

えいー)= えい+やい[p(i)(も)-p(i)(も)],

Where the first r rows of Dill are the first r rows of the matrix P(1) and the last (n-r) rows of Dil are

6-4 (conti) the last (n-r) rows of P(i) . Setting 是(1+1) = 至d and solving for p(1+1)(to) gives

果(i+1)(to)= 果(i)(to) -[D(i)]-「[走(i)-美」]

Thus, solving this problem is simply a matter of using some entries of Rp and some entries of Rx.

Integrating from to to we can use the dependence of x(to) on x(tx) to derive the iteration equation. This dependence is indicated by

 $\chi(t_0) = \int_{\mathbb{R}} (\chi(t_0)).$ 

Expanding in a taylor series and retaining only terms of up to first order, we have

 $\chi^{(i+1)}(t_0) = \chi^{(i)}(t_0) + \left[\frac{\partial f}{\partial \chi}(\chi^{(i)}(t_p))\right] \left[\chi^{(i+1)}(t_p) - \chi^{(i)}(t_p)\right].$ 

Setting x (iti) (to) = xo , the specified (and hence desired) value of X(to), and solving for X (i+1) (tx) yields

 $\mathcal{Z}_{(1+1)}(\mathbf{f}^2) = \mathcal{Z}_{(1)}(\mathbf{f}^2) - \left[\frac{3\times}{3}(\mathcal{Z}_{(1)}(\mathbf{f}^2))\right]_{(1+1)} \left[\mathcal{Z}_{(1)}(\mathbf{f}^2) - \mathcal{Z}_{(2)}(\mathbf{f}^2)\right]$ 

To generate the nxn matrix  $\frac{\partial f}{\partial x}$  (x<sup>(i)</sup>(4)) we start with the reduced differential equations

$$\dot{\chi}(t) = \frac{\delta \mathcal{L}}{\delta \mathcal{L}} (\chi(t), \varphi(t), t)$$

$$\dot{\mathcal{Z}}(t) = -\frac{3}{3}(3(t),\mathcal{Z}(t),t)$$

and take the partial derivatives of both sides with respect to  $x(t_f)$ . Interchanging the order of differentiation on the left and using the chain rule on the right gives

$$\frac{df}{d} \left[ \frac{9 \times (f^2)}{9 \times (f^2)} \right] = \left[ \frac{9 \times 9 \cdot f}{9 \cdot 5 \cdot f} \right] \frac{9 \times (f^2)}{9 \times (f^2)} + \left[ \frac{9 \cdot 5 \cdot f}{9 \cdot 5 \cdot f} \right] \frac{9 \times (f^2)}{9 \times (f^2)}$$
 (II)

$$\frac{4t}{4} \left[ \frac{9\ddot{x}(t^2)}{2^{\frac{1}{2}(t^2)}} \right] = - \left[ \frac{9\ddot{x}_1}{9^{\frac{1}{2}(t^2)}} \right] \frac{9\ddot{x}(t^2)}{9\ddot{x}(t^2)} - \left[ \frac{9\ddot{x}_2)5}{9^{\frac{1}{2}(t^2)}} \right] \frac{9\ddot{x}(t^2)}{9^{\frac{1}{2}(t^2)}} \ .$$

The arguments of the second partials of X have been omitted. The boundary conditions are

$$\frac{\partial \chi(t_f)}{\partial \chi(t_f)} = \frac{1}{2} \quad \frac{\partial \chi(t_f)}{\partial \chi(t_f)} = 0 \quad (assuming)$$

h=0 in the performance measure). The matrix  $\partial f/\partial x$  appearing in (I) is  $\partial x(to)/\partial x(to)$ , the solution of (II) at t=to.

(b) Select x(to) = 0 because I indicates a desire to bring the state hear the origin. If the system is controllable and the penalty on control effort expenditure is not too severe, we would hope that x(to) would at east be close to the origin.

6-6
Substitute the given y(t) into the D.E. and see if it reduces to an identity, that is,

Performing the differentiation indicated on the left gives

在[其(t)]=c,是[至H(t)]+···+cg是[圣H8(t)]+虚[至时].

But, by definition of ZH(t), ..., Z (t),

를 [공바(t)] = 모(t)로(t) (t) , i=17,11,19

== D(t) = P(t) = P(t) + P(t).

Therefore

世[其代]=c,及代圣性(七)+···+cg及代圣姆(出现此圣佛性

= D(A) [c1x4,(A)+...+c6x4,(A)+x6,(A)+x6,(A)]+x(A)

▲ 只由 关(日) + 壬(日),

which is the right side of (I); hence, the specified 4(t) is a solution of the D.E.

6-7

we generate the n homogeneous solutions and the particular solution to the linearized reduced D.E. as usual. Then,

165

 $\chi(t) = c_1 \chi^{H1}(t) + c_2 \chi^{H2}(t) + \dots + c_n \chi^{Hn}(t) + \chi^{P}(t)$  (1)

 $\mathcal{L}(t) = c_1 \mathcal{L}^{H1}(t) + c_2 \mathcal{L}^{H2}(t) + \dots + c_n \mathcal{L}^{Hn}(t) + \mathcal{L}^{P}(t)$ . (17)

If p(tf) were known we would solve for ci, cz,..., on and obtain the result

given in Eq. (6.4-35) of the text.

Here, since x(tf) = xf is specified, we have from (I)

 $\chi(t_g) = \chi_f = \left[\chi^{H_1}(t_g), \chi^{H_2}(t_g), \dots, \chi^{H_n}(t_g)\right] + \chi^{P}(t_g)$ 

solving for a, we obtain

$$\mathcal{L} = \left[ \chi_{\text{H}_1}(f^2) \right] \cdots \left[ \chi_{\text{H}_2}(f^2) \right] - \left[ \chi_{\text{L}} - \chi_{\text{L}}(f^2) \right].$$

we generate the n homogeneous solutions and the particular solution as usual

to obtain (I) and (II) given in the solution to Problem 6-7. Suppose that

$$x'(f^2) = x'^2$$
  $x^2(f^2) = x^{-2}$   $\dots$   $x^{-1}(f^2) = x^{-2}$ 

Pr+1(ts) = pr+15, ..., pn(ts) = pns are specified values. Let

then n of the equations (I) and (II)

can be written at tets as

 $\xi(t_g) = c_1 \xi^{H'}(t_g) + \dots + c_n \xi^{H''}(t_g) + \xi^{P}(t_g)$ 

6-8 (cont.) Everything on the right side is known except the c's jon the left side  $\mathbf{Z}(\mathbf{t}_f) = \mathbf{Z}_f$  (the specified value). Solving for & gives 6-9 For simplicity assume H= Q, then Plan since the final states are free. In this case the reduced D.E. are linear and homogeneous, that is, they are of the form  $\dot{\chi}(t) = \dot{\chi}(t) \dot{\chi}(t) + \dot{\chi}(t) \dot{\varphi}(t)$  $(\pm)$  $(\mathbb{T})$ 主(t)= 是(t) &(t) + 免(t) 平(t). Using the reasoning of Problem 6-6 we can show that  $c_1 \propto^{H_1}(t) + \cdots + c_n \propto^{H_n}(t) + \propto^{H(n+i)}(t)$ is a solution of (I) and c, pH(t)+...+ cnp Hn(t) + pH(n+1)(t) (t) is la solution of Eq. (II).

XH(n+1)(t), pH(n+1)(t) is the solution of (I) and (II) that satisfies the boundary conditions & H(n+1) (to) = X0 and RH(n+1) (to) = Q. The other n

homogeneous solutions are generated

6-9 (cont.)

as usual. Now, since  $p(t_s) = Q$  we can set the quantity (t) equal to Q and solve for E, which gives

$$\mathcal{L} = -\left[ \mathcal{L}^{H}(t_{\mathcal{G}}) \right] \cdots \left[ \mathcal{L}^{H}(t_{\mathcal{G}}) \right] \mathcal{L}^{H(N+1)}(t_{\mathcal{G}}).$$

For these values of the c's the specified boundary conditions are satisfied by a solution of (I) and (II); hence, a solution has been obtained in one iteration.

6-10

The starting point is the equations  $\chi(t_f) = c_1 \chi^{HI}(t_f) + ... + c_n \chi^{HI}(t_f) + \chi^P(t_f)$  (I)

The iteration index is understood to be (i+1). We will assume that x/4) is free, (a) Since x(tx) is free, the final costate is

 $\mathcal{R}^{(i+1)}(t_f) = 2 \, \text{lf} \, \chi^{(i+1)}(t_f) \, .$ 

Multiplying the right side of (I) by 2H and equating this to the right side of (II) gives (after rearranging terms)

CI[RH(tg)-2HXH(tg)]+...+cn[RHN(tg)-2HXHN(tg)]=2HXHg)-P(tg).

168

Solving for £ ≜ [c, c2...cn] gives

E=[++(+5)-2性文+(+5)]---|++n(+5)-2共文+n(+5)]-[2共文P(+5)-+P(+5)].

(b) Here we have  $P^{(i+1)}(+\xi) = \frac{\partial X}{\partial h} (X^{(i+1)}(+\xi)) \triangleq \frac{\partial X}{\partial h}$ 

As in the solution to Problem 6-1, we expand R(tg) in a Taylor

series to obtain

 $\mathcal{L}_{(i+1)}(f^2) = \frac{9^{1/2}}{9^{1/2}} \left( \mathcal{L}_{(i)}(f^2) \right) + \left[ \frac{9^{1/2}}{9^{5/2}} \left( \mathcal{L}_{(i)}(f^2) \right) \right] \left[ \mathcal{L}_{(i+1)}(f^2) - \mathcal{L}_{(i)}(f^2) \right]$ 

 $\triangleq \frac{\partial h^{(c)}}{\partial x^{(c)}} + M \left[ \chi^{(c+1)}(t_f) - \chi^{(c)}(t_f) \right]$ 

 $= \frac{\lambda \kappa}{\partial h^{(1)}} - M \times (i)(t_f) + M \times (i+1)(t_f).$ 

Substituting the right side of (I) for X(1+1)(tx) in (III) and equating the right side of (III) to the right side of (III) yields

 $c_1 \mathcal{R}^{HI}(t_{\xi}) + \cdots + c_n \mathcal{R}^{Hn}(t_{\xi}) + \mathcal{R}^{P}(t_{\xi}) = \frac{\partial h^{(L)}}{\partial x} - \text{M} x^{(L)}(t_{\xi})$ 

+M[c,&"(ts)+...+cn&"(ts)+&"(ts)] Rearranging terms and solving for & gives C = [24(4)-MXH(4)]...|24"(4)-MXH(4)]- [31(1) -MX(1)(4) + M X P(好) - R P(好) ](四) 6-10 (cont.) Which is Eq. (6.4-38) of the text.

(c) To obtain the result obtained in part (a), substitute

$$M = 2 \pm \sqrt{\frac{3h^{(i)}}{3x}} = 2 \pm 3^{(i)}(4)$$

into (IV). To obtain Eq. (6.4-35) of the text, substitute

$$X = Pf$$
 for  $\frac{\partial h^{(i)}}{\partial X}$  (since  $h = X^T X(H_F)$ ) and  $M = Q$  into Eq. (IX).

6-11

We have a two-point boundary-value problem of the form

$$\dot{\mathcal{Z}}(t) = \mathcal{A}(t) \, \mathcal{Z}(t) + \mathcal{D}(t) \, \mathcal{Z}(t) + \mathcal{D}_{1}(t) \qquad (T)$$

$$\dot{p}(t) = E(t) \chi(t) + E(t) p(t) + m_2(t) \quad (\pm)$$

which is similar to the equations encountered in the linear tracking problem. We postulate that

$$\mathcal{R}^{(t)} = \mathcal{K}^{(t)} \mathcal{L}^{(t)} + \mathcal{L}^{(t)}, \qquad (\pi t)$$

where K is a nxn real symmetric matrix and ZH is an n vector.

Differentiating (IIII) with respect to time yields

Substituting for p(t) and x(t) from (I) and (II) seliminating P(t) by substi-

tution of (III), and collecting terms yields  $Q = [E(t) - \dot{K}(t) - K(t) A(t) - K(t) D(t) K(t)] \chi(t) + M_2(t)$ 

- K(t)M,(t)-\$(t)+[G(t)-K(t)R(t)]\$(t). (IV)
Since this equation must hold for all
X(t), M, (t) and M2(t), the coefficient of
X(t) must be zero, and the other terms
must add to zero; thus,

 $\dot{K}(t) = E(t) - K(t)A(t) + E(t)K(t) - K(t)D(t)K(t)E$ and

美田= [天生)-火生) 女生] 文生)-火生) ぬ,生)+ぬ2(七)(四)

Assuming that X(tf) is free, the boundary conditions for (I) and (II) are

 $\mathcal{Z}^{(i+i)}(t_{\tau}) = \frac{\partial h}{\partial \chi} \left( \chi^{(i)}(t_{\tau}) - M \chi^{(i)}(t_{\tau}) + M \chi^{(i+i)}(t_{\tau}) \right)$ (See Problem 67:0).

From (VII) and (III) the boundary conditions

for (X) and (VII) are

$$K(f^{\sharp}) = \widetilde{W} \stackrel{\partial}{=} \frac{9^{\sharp}}{9^{\sharp}} (\mathscr{X}_{(f)}(f^{\sharp})) \qquad (AIII)$$

and

$$\lesssim (t_{\xi}) = \frac{\partial h}{\partial x} \left( \chi^{(i)}(t_{\xi}) - M \chi^{(i)}(t_{\xi}) \right). \quad (IX)$$

To obtain p(to) integrate (V) and (VI) from to to using the boundary conditions (VIII) and (IX). Then, from (III), P(to) = K(to) X(to) + x(to).

The reduced D.E. are of the form

$$\dot{X}(t) = A(t) X(t) + D(t) x(t)$$

$$\dot{\mathcal{F}}(t) = \mathcal{E}(t) \, \chi(t) + \mathcal{C}(t) \, \mathcal{F}(t),$$

or, defining &(t) = [x(t) | p(t)], we have

$$\dot{\mathbf{z}}(t) = \mathbf{z}(t) \mathbf{z}(t) \tag{T}$$

which has a solution of the form

where Y(t, to) is the transition matrix for the system (I). Y (t) to) can be determined by integrating

with the initial condition I(to) = I.

we also know that

$$\mathcal{L}(t) = \mathcal{K}(t) \mathcal{L}(t) \tag{1}$$

for all t; K(t) is the solution of the Riccati equation. At t = to we have

$$\mathcal{L}(t_0) = \mathcal{K}(t_0) \otimes (t_0)$$
.

If we select x"(+0) = [100...0] , then

$$\mathcal{R}^{(1)}(t_0) = \begin{bmatrix} k_{11}(t_0) \\ k_{21}(t_0) \\ \vdots \\ k_{n1}(t_0) \end{bmatrix}.$$

6-12 (cont.) More generally, for & (to) = [00...10...0]

we have  $p^{(i)}(t_0) = \begin{bmatrix} k_{1i}(t_0) \\ k_{2i}(t_0) \end{bmatrix}, \text{ the ith column} \\ \vdots \\ k_{ni}(t_0) \end{bmatrix}, \text{ of } \chi(t_0) \text{ at } t = t_0.$ 

If we can find the  $p^{(i)}(t_0)$  which corresponds to  $x^{(i)}(t_0)$ , the matrix x(t) will be known at  $t=t_0$ .

From Eq. (II) with t=to we have

$$\begin{bmatrix} \chi(t_{g}) \\ \chi(t_{g}) \end{bmatrix} = \begin{bmatrix} \chi_{11}(t_{g}, t_{0}) & \chi_{12}(t_{g}, t_{0}) \\ \chi_{21}(t_{g}, t_{0}) & \chi_{22}(t_{g}, t_{0}) \end{bmatrix} \begin{bmatrix} \chi(t_{0}) \\ \chi(t_{0}) \end{bmatrix}$$

which implies that for the specified value of x(4x) (i.e. xx),

 $X^{\dagger} = \tilde{\chi}_{11}(f^{\dagger}) f^{0} \tilde{\chi}_{(1)}(f^{0}) + \tilde{\chi}_{12}(f^{\dagger}) f^{0} \tilde{\chi}_{(1)}(f^{0})$ solving for p(i)(to) gives

$$p^{(i)}(t_0) = \chi_{12}^{-1}(t_5, t_0) \left[\chi_5 - \chi_1(t_5, t_0) \chi^{(i)}(t_0)\right]$$

Thus, we can use Eq. (IV) to determine K (to); the Riccati equation can then be solved for tostst, <tf by integrating from to to ti (ti is the time when the solution for K(t) begins to exceed the allowable range of numbers for the computer used to

6-12 (cont.)
generate the solution).

6-14

The constraints can be written as

$$\begin{bmatrix} 1 & 0 & 0 & -1 & 1 & 1 \\ 0 & 1 & 0 & -1 & 1 & -2 \\ 0 & 0 & 1 & -1 & -1 & 0 \end{bmatrix} \xrightarrow{T} y = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & -1 & 0 \end{bmatrix} \xrightarrow{2} 0 ;$$

hence, in the normalized version of these constraints

$$N_{L} = \begin{bmatrix} 1 & 0 & 0 & -.5774 & .5774 & .4472 \\ 0 & 1 & 0 & -.5774 & .5774 & -.8944 \\ 0 & 0 & 1 & -.5774 & -.5774 & 0 \end{bmatrix}$$

and

(i) If  $y^{(0)} = [2.0 50.0 17.0]^{T}$  (not an admissible point), the algorithm first corrects back to the admissible point  $y^{'(0)} = [0.666 \ 0.3333 \ 0.0]^{T}$ ; the next point found is

y(1) = y \*= [0.3333 0.1666 0.500]T.

((i) For y(0) = [50.0 2.0 -2.0] the algorithm first corrects back to the admissible point

$$y'^{(0)} = \begin{bmatrix} 1.0 & 0.0 & 0.0 \end{bmatrix}^{T}$$
and then finds

and then finds 
$$y^{(1)} = [0.5 \quad 0.0 \quad 0.5]^T$$

 $y^{(2)} = y^* = [0.3333 \ 0.166 \ 0.5000]^T$ . For both (i) and (ii)  $f(y^*) = 2.167$ .

6-16

The constraints are

where  $\mathbb{I}_q$  is the 9x9 identity matrix and  $\mathbb{Q}_q$  is the 9-dimensional zero vector.

The computer program normalizes these constraints before beginning the computations.

(i) For  $\chi^{(0)} = Q$ , which is an admissible point, the next point is

y(1) = y\* = [0. .5 0. .25 .25 0. .1666 0. 1.].

(ii) For  $y^{(0)} = [1, 2, 0, 0, 5, 4, 0, 0, 1]^T$ (not an admissible point), the algorithm first corrects to the admissible point  $y^{(0)} = [0, .5, 0, 0, 5, 4, 0, 0, 1]^T$ .

Then, the next point generated is

 $y^{(1)} = \begin{bmatrix} .0217 & .4732 & .0485 & .0606 & .2474 & 0. & .0970 \\ .0606 & .98987 \end{bmatrix}$ 

and

 $y^{(2)} = \begin{bmatrix} .0323 & .4600 & .1022 & .1278 & .2462 & 0, \\ .1150 & .0383 & .9848 \end{bmatrix}^{T}$ 

 $y_{\alpha}^{(3)} = \begin{bmatrix} .0279 & .4655 & .0905 & .1422 & .2467 & 0. \\ & .1551 & 0. & .9868 \end{bmatrix}^{T}$ 

 $y^{(5)} = y^* = [0..5 \ 0..25 \ .25 \ 0...1666 \ 0...1]^T;$   $f(y^*) = 0.1458.$ 

In addition to the two linear constraints we have a nonlinear constraint of the form  $g(y) \ge 0$  which we linearize by expanding g in a Taylor series about the point g(i) (which is known) and retaining terms of up to first order, that is,  $g(y(i+1)) = g(y(i)) + \left[\frac{\partial g}{\partial y}(y(i))\right] \left[y(i+1) - y(i)\right]$ .

Performing the indicated operations and collecting terms we obtain

$$\begin{bmatrix} -4y_{1}^{(1)} \end{bmatrix}^{T} y_{1}^{(1+1)} - \begin{bmatrix} -2[y_{1}^{(1)}]^{2} - 3[y_{2}^{(1)}]^{2} - 6 \end{bmatrix} \ge 0;$$

hence, the constraints are

$$\begin{bmatrix} 1 & 0 & -4y_1^{(i)} \\ 0 & 1 & -6y_2^{(i)} \end{bmatrix} y_1^{(i+1)} - \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -2[y_1^{(i)}]^2 - 3[y_1^{(i)}]^2 - 6 \end{bmatrix} \ge 0.$$

At the end of each minimization y ii), which appears in the above constraints, is replaced by the new value of y, the constraints are normalized, and the algorithm begins a new iteration. The initial guess was [10 2]T. Then

$$y'^{(0)} = [5.275 .5826]^{T}$$
 $y'^{(1)} = [.9415 1.089]^{T}$ 
 $y'^{(2)} = [2.114 11.11]^{T}$ 
 $y'^{(3)} = [0.0 18.16]^{T}$ 

$$g^{(3)} = [0.0 9.138]^{T}$$
 Iteration 2  
 $g^{(4)} = [1.0 9.138]^{T}$  Iteration 2  
 $g^{(4)} = [.6737 4.666]^{T}$  Iteration 3  
 $g^{(5)} = [.9635 4.644]^{T}$ 

y (5) = [.6686 2.512] | Iteration 4 y (6) = [.9308

支((6) = [.7067 1.581]T }
1.539]T }
Iteration 5 ਖ਼ੂ<sup>(7)</sup> = [.8747

6-17 (cont.)

$$y'^{(7)} = [.7801 \quad 1.289]^{T}$$
 $y'^{(8)} = [.8106 \quad 1.278]^{T}$ 
 $y'^{(8)} = [.8006 \quad 1.254]^{T}$ 
 $y'^{(8)} = [.7885 \quad 1.259]^{T}$ 
 $y'^{(8)} = [.7886 \quad 1.259]^{T}$ 
 $y'^{(8)} = [.7886 \quad 1.259]^{T}$ 
 $y'^{(9)} = [.7913 \quad 1.258]^{T}$ 

Iteration 8

 $y'^{(10)} = [.7904 \quad 1.258]^{T}$ 

Iteration 9

 $y'^{(10)} = y'' = [.7907 \quad 1.258]^{T}$ 

6-19 through 6-22

The curves of the optimal trajectory and control are given on the following page.

丁米= 13.5140
